Developmental neurotoxicity of industrial chemicals

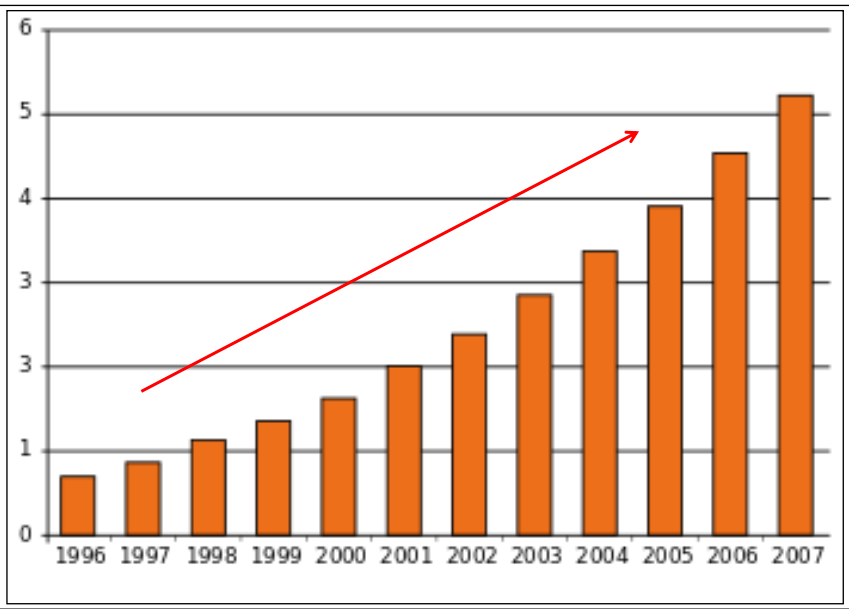
P Grandjean, PJ Landrigan

Neurodevelopmental disorders such as autism, attention deficit disorder, mental retardation, and cerebral palsy are common, costly, and can cause lifelong disability. Their causes are mostly unknown. A few industrial chemicals (eg, lead, methylmercury, polychlorinated biphenyls [PCBs], arsenic, and toluene) are recognised causes of neurodevelopmental disorders and subclinical brain dysfunction. Exposure to these chemicals during early fetal development can cause brain injury at doses much lower than those affecting adult brain function. Recognition of these risks has led to evidence-based programmes of prevention, such as elimination of lead additives in petrol. Although these prevention campaigns are highly successful, most were initiated only after substantial delays. Another 200 chemicals are known to cause clinical neurotoxic effects in adults. Despite an absence of systematic testing, many additional chemicals have been shown to be neurotoxic in laboratory models. The toxic effects of such chemicals in the developing human brain are not known and they are not regulated to protect children. The two main impediments to prevention of neurodevelopmental deficits of chemical origin are the great gaps in testing chemicals for developmental neurotoxicity and the high level of proof required for regulation. New, precautionary approaches that recognise the unique vulnerability of the developing brain are needed for testing and control of chemicals.

A few industrial chemicals (eg, **lead, methylmercury, polychlorinated biphenyls [PCBs], arsenic**, and **toluene**) were recognized causes of neurodevelopmental disorders and subclinical brain dysfunction.

Twelve years ago two well-known experts in *Environmental Health*, a pediatrician and an epidemiologist, launched an alarm from the pages of ***the Lancet***, affirming that a ***silent pandemic* of neurodevelopmental disorders** was spreading, also due to the *shortage of funds in this area of research*

In fact the reports of autism cases per 1,000 children had increased dramatically over the years in the U.S. from 1996 to 2007



Newschaffer CJ, Croen LA, Daniels J et al. ***The epidemiology of autism spectrum disorders*** Annu Rev Public Health. 2007;28:235–58.

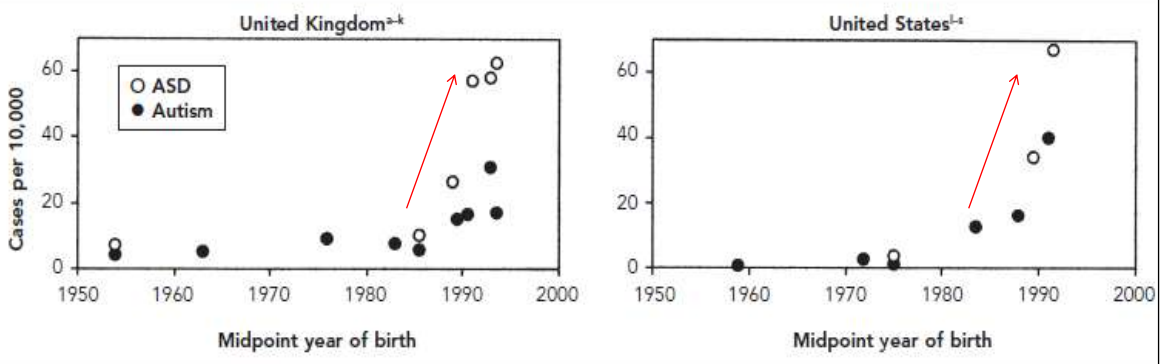
AUTISM
(ASD :Autism Spectrum Disorders)

ASD is the fastest-growing developmental disorder in the world, the prevalence of diagnosis having increased by 600% over the last 20 years. New diagnosed cases (**incidence**) in US increased **from 15,580 in 1992 to 163.773 in 2003**

The estimated **prevalence was of 8-12 cases/1000 children in 2012..**

Chart showing the **increase in autism diagnosis (A)** ***versus*** **all disabilities (B)** (statistics based on data from the National Center for Health Statistics)

Figure 1. Reported prevalence of autism and autistic spectrum disorders (ASDs), by midpoint year of birth, United Kingdom and United States, 1954–1994



NOTE: These graphs show prevalence estimates from 11 U.K. and 8 U.S. studies. For studies with survey populations spanning a range of birth years, the midpoint of the birth year range is used.

Neurobehavioural effects of developmental toxicity

Philippe Grandjean, Philip J Landrigan

Neurodevelopmental disabilities, including autism, attention-deficit hyperactivity disorder, dyslexia, and other cognitive impairments, affect millions of children worldwide, and some diagnoses seem to be increasing in frequency. Industrial chemicals that injure the developing brain are among the known causes for this rise in prevalence. In 2006, we did a systematic review and identified five industrial chemicals as developmental neurotoxicants: lead, methylmercury, polychlorinated biphenyls, arsenic, and toluene. Since 2006, epidemiological studies have documented six additional developmental neurotoxicants—manganese, fluoride, chlorpyrifos, dichlorodiphenyltrichloroethane, tetrachloroethylene, and the polybrominated diphenyl ethers. We postulate that even more neurotoxicants remain undiscovered. To control the pandemic of developmental neurotoxicity, we propose a global prevention strategy. Untested chemicals should not be presumed to be safe to brain development, and chemicals in existing use and all new chemicals must therefore be tested for developmental neurotoxicity. To coordinate these efforts and to accelerate translation of science into prevention, we propose the urgent formation of a new international clearinghouse.

The same two authors returned to the problem **seven years later, with a broad review published the Lancet Neurology (2014)**

Since 2006, epidemiological studies have documented **six additional developmental neurotoxicants — manganese, fluoride, chlorpyrifos, tetrachloroethylene, dichlorodiphenyltrichloroethane, and the polybrominated diphenyl ethers.**
We postulate that even more neurotoxicants remain undiscovered

Community Report on Autism 2018

Centers for Disease Control and Prevention

Community Report from the **Autism and Developmental Disabilities Monitoring (ADDM) Network**

ADDM Network

1.7% is the average percentage identified with ASD

1 in 59 8-year-old children were identified with ASD by ADDM in 2014

Why is this information important and how can it be used?

1. Lower the age of first evaluation by community providers; and
2. Increase awareness of ASD among black and Hispanic families, and identify and address barriers in order to ensure that all children with ASD are evaluated, diagnosed, and connected to services.

PEDIATRICS
OFFICIAL JOURNAL OF THE AMERICAN ACADEMY OF PEDIATRICS

The Prevalence of Parent-Reported Autism Spectrum Disorder Among US Children

Michael D. Kogan, PhD,[a] Catherine J. Vladutiu, PhD, MPH,[a] Laura A. Schieve, PhD,[b] Reem M. Ghandour, DrPH,[a] Stephen J. Blumberg, PhD,[c] Benjamin Zablotsky, PhD,[c] James M. Perrin, MD,[d] Paul Shattuck, PhD,[e] Karen A. Kuhlthau, PhD,[d] Robin L. Harwood, PhD,[a] Michael C. Lu, MD, MPH[f]

OBJECTIVES: To estimate the national prevalence of parent-reported autism spectrum disorder (ASD) diagnosis among US children aged 3 to 17 years as well as their treatment and health care experiences using the 2016 National Survey of Children's Health (NSCH).

METHODS: The 2016 NSCH is a nationally representative survey of 50 212 children focused on the health and well-being of children aged 0 to 17 years. The NSCH collected parent-reported information on whether children ever received an ASD diagnosis by a care provider, current ASD status, health care use, access and challenges, and methods of treatment. We calculated weighted prevalence estimates of ASD, compared health care experiences of children with ASD to other children, and examined factors associated with increased likelihood of medication and behavioral treatment.

RESULTS: Parents of an estimated 1.5 million US children aged 3 to 17 years (2.50%) reported that their child had ever received an ASD diagnosis and currently had the condition.

CONCLUSIONS: The estimated prevalence of US children with a parent-reported ASD diagnosis is now 1 in 40, with rates of ASD-specific treatment usage varying by children's sociodemographic and co-occurring conditions.

New genetic risk factor for developing autism spectrum disorder identified

Date: August 31, 2017

Source: Oregon Health & Science University

Summary: A new systematic analysis has been applied to a cohort of 2,300 families who have a single child affected with autism. The study focused on identifying and characterizing low-lying genetic mutations that may have been missed in previous research, given these mutations are only present in a fraction of the bulk DNA of an individual.

tematic analysis to a cohort of 2,300 families who have a single child affected with autism. The study focused on identifying and characterizing low-lying genetic mutations that may have been missed in previous research, given these mutations are only present in a fraction of the bulk DNA of an individual.

Known as postzygotic mosaic mutations, or PMMs, these genetic changes occur after the conception of the human zygote during the development cycle of a fetus. An individual will contain a mosaic -- or assortment -- of mutated and non-mutated cells with the level of mosaicism depending on the time and location of the mutation's occurrence. This emerging class of genetic risk factors has recently been implicated in various neurologic conditions, however,

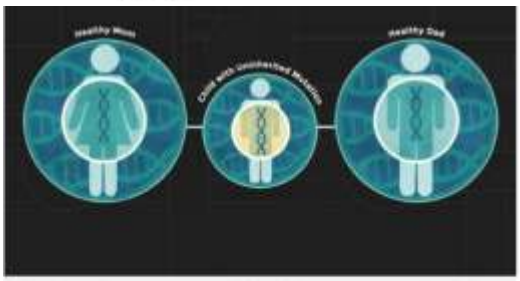
Autism genetics study calls attention to motor skills, general cognitive impairment

Date: February 7, 2018

Source: Cold Spring Harbor Laboratory

Summary: A new study of the genetic factors involved in the causation of autism spectrum disorders (ASD) draws fresh attention to the impact these illnesses have on motor skills, and more broadly on cognitive function. Careful inference from the data suggests to researchers that the genetic factors causing ASD broadly diminish the brain's cognitive functions.



Mutations that appear in a child which are not present in either parent -- called de novo mutations -- can be important in autism. Severe, gene-disrupting de novo mutations are thought to be capable of causing the disorder in certain instances. New research shows that diminished motor skills, like low non-verbal IQ, correlate with the severity of de novo mutations. More broadly the study calls attention to role played by genetics in di-

…or in this case: **new mutations disturbing motor functions** could be important in ***autism*** **...!!??!!**

IMPORTANCE The origins and development of autism spectrum disorder (ASD) remain unresolved. No individual-level study has provided estimates of additive genetic, maternal, and environmental effects in ASD across several countries.

OBJECTIVE To estimate the additive genetic, maternal, and environmental effects in ASD.

DESIGN, SETTING, AND PARTICIPANTS Population-based, multinational cohort study including full birth cohorts of children from Denmark, Finland, Sweden, Israel, and Western Australia born between January 1, 1998, and December 31, 2011, and followed up to age 16 years. Data were analyzed from September 23, 2016 through February 4, 2018.

MAIN OUTCOMES AND MEASURES Across 5 countries, models were fitted to estimate variance components describing the total variance in risk for ASD occurrence owing to additive genetics, maternal, and shared and nonshared environmental effects.

RESULTS The analytic sample included 2 001 631 individuals, of whom 1 027 546 (51.3%) were male. Among the entire sample, 22 156 were diagnosed with ASD. The median (95% CI) ASD heritability was 80.8% (73.2%-85.5%) for country-specific point estimates, ranging from 50.9% (25.1%-75.6%) (Finland) to 86.8% (69.8%-100.0%) (Israel). For the Nordic countries combined, heritability estimates ranged from 81.2% (73.9%-85.3%) to 82.7% (79.1%-86.0%). Maternal effect was estimated to range from 0.4% to 1.6%. Estimates of genetic, maternal, and environmental effects for autistic disorder were similar with ASD.

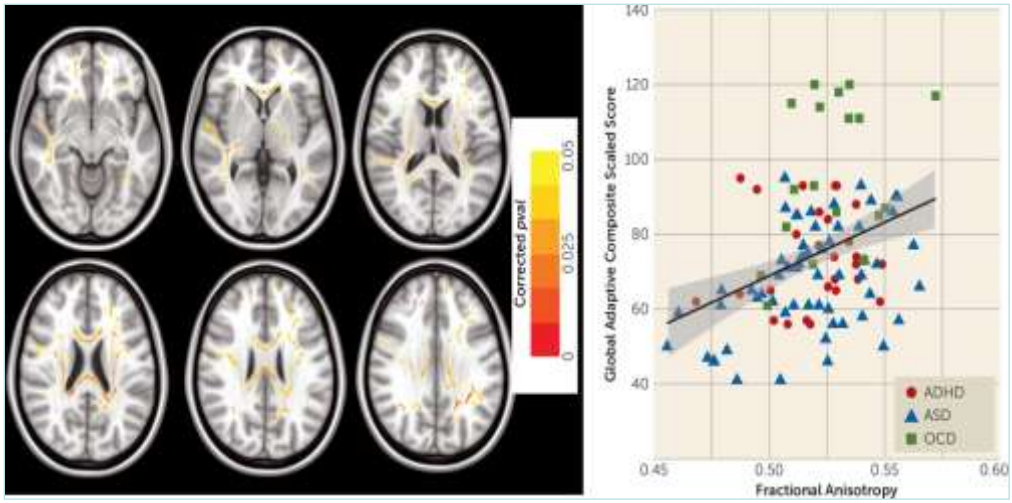
CONCLUSIONS AND RELEVANCE Based on population data from 5 countries, the heritability of ASD was estimated to be approximately 80%, indicating that the variation in ASD occurrence in the population is mostly owing to inherited genetic influences, with no support for contribution from maternal effects. The results suggest possible modest differences in the sources of ASD risk between countries.

Heritability estimates ranged from **81.2%**(73.9%-85.3%) to 82.7% (79.1%- 86.0%). ***Maternal effect*** was estimated to range from ***0.4% to 1.6%.***

Autism, ADHD and **OCD** have **common symptoms** and **are linked by some of the same genes**.

Yet they have always been considered as separate disorders

a continuum…



Children with autism and ADHD showed more severe impairments affecting more of the brain's white matter than those with OCD. This finding may reflect the fact that both autism and ADHD typically have an onset at a much younger age than OCD, and at a time when a number of different white matter tracts are going through rapid development.

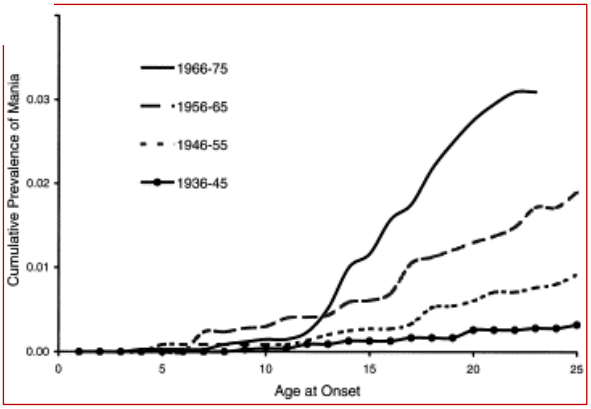
The unmet needs in diagnosis and treatment of mood disorders in children and adolescents

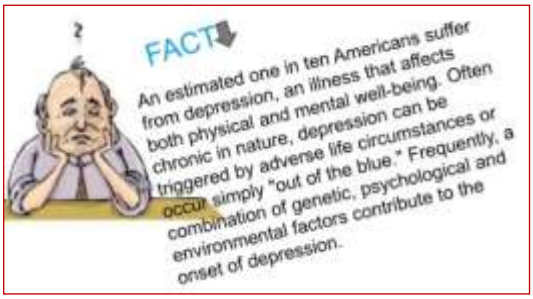
Mood disorders in children and adolescents: an epidemiologic perspective

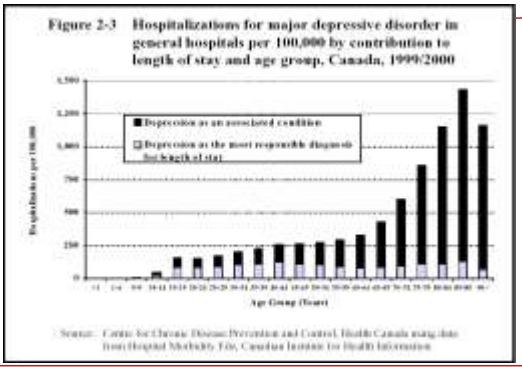
Ronald C Kessler [a,*], Shelli Avenevoli [b], Kathleen Ries Merikangas [b]

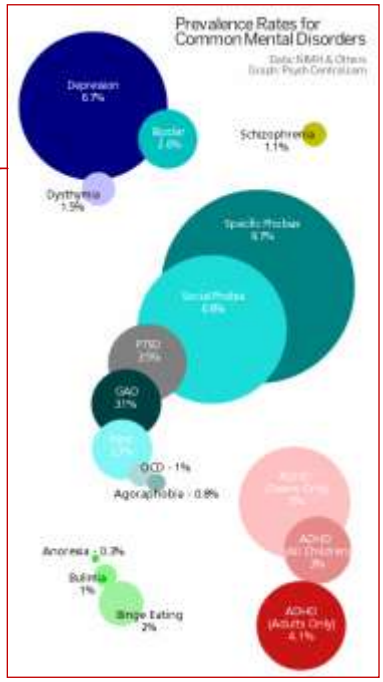
Adolescence is a time of increasing vulnerability for severe mental health disorders such as depression.
Epidemiological studies show that the **incidence of new cases of depression drastically increases with puberty..** Importantly, there is growing evidence that **sleep disturbance in adolescence may predict the development of depression**.. In addition to the increase in the prevalence of depression with the transition from childhood to adolescence, **there is also a secular trend of an increasing incidence of depression during adolescence since the 1960s**



http://www.slideshare.net/CMoondog/depression-powerpoint-13945746



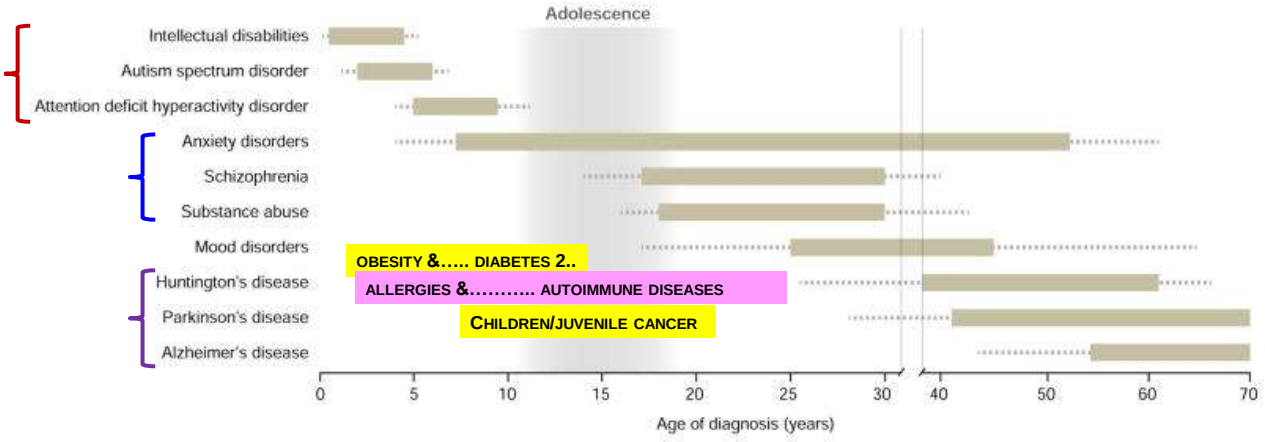




http://psychcentral.com/blog/archives/2009/10/05/prevalence-of-common-mental-disorders/

Psychiatric and Neurological disorders Have Discrete Ages of Onset (but represent a *continuum*)..
the most interesting and mysterious aspect of the DOHaD model is that their origin is during the fetal-embryo period (*fetal programming*) as for all other chronic diseases that are dramatically increasing in the world (Obesity & Diabetes 2.. Allergies & Autoimmune diseases.. Cancer..) ... which means: *EPIGENETICS > GENETICS*

*….it's almost like **a time bomb** ..*



Silbereis JC, Pochareddy S, Zhu Y, Li M, Sestan N. ***The Cellular and Molecular Landscapes of the Developing Human Central Nervous System***. Neuron. 2016;89(2):248–268. doi:10.1016/j.neuron.2015.12.008

"The womb may be more important than the home"
David Barker

This new paradigm is important not only to explain in a more exhaustive way the embryo-foetal origins of all the above mentioned disorders and their dramatic increase over the last decades, but also to try to effectively face this epidemiological transition. The key-term in this context is certainly primary prevention: only by reducing the maternal-foetal factors of distress and the exposure of the foetus (and of its gametes) to pollutants, it would be possible to protect the correct programming of cells, tissues and organs.

The key-term in this context is certainly ***primary prevention***

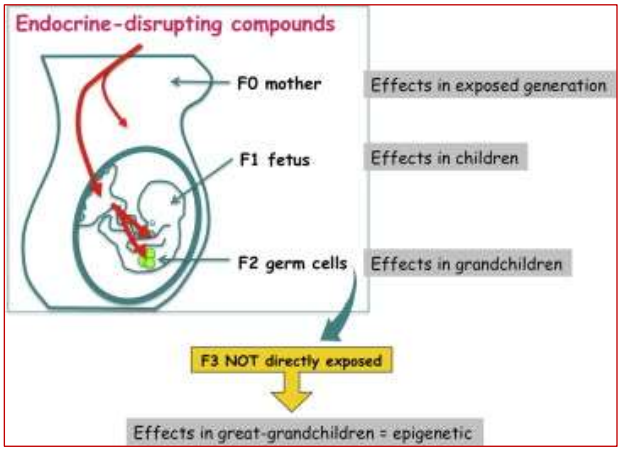
ECERI - European Cancer and Environment Research Institute

A significant, dramatic case: for some years I have been invited to Martinique, a small paradise in the Atlantic Ocean, to investigate **the origins of the continuous increase of Cancer** (in Martinique there is **the world record of prostate CA**) and **Autism in children**…

Last year, at the **last congress,** I asked **three questions:**

Question 1

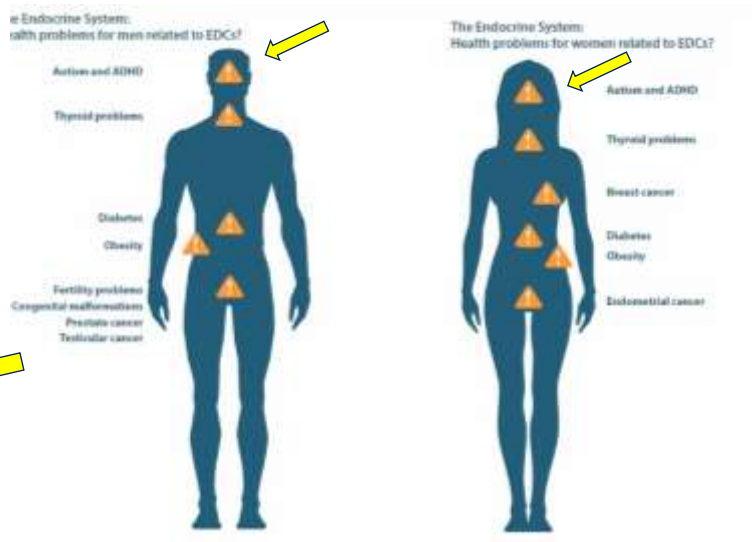
- To what extent the **exposure of moms and fetuses to endocrine disruptors and other epigenotoxic molecules that interfere with *fetal programming*** represents a **serious threat** to the **health of children and *future generations*** ?



https://www.sciencedirect.com/science/article/pii/S0303720711006356

Question 2

What is the role of the ever increasing exposure of moms and fetuses to epi-genotoxic molecules in the genesis of the current ***Epidemiological Transition***: Pandemics of ***obesity*** and ***juvenile diabetes 2*** , continuous increase in ***allergic and autoimmune diseases***, ***neuro-developmental disorders***, ***neurodegenerative diseases*** and ***cancer*** (especially in infants and young people)?

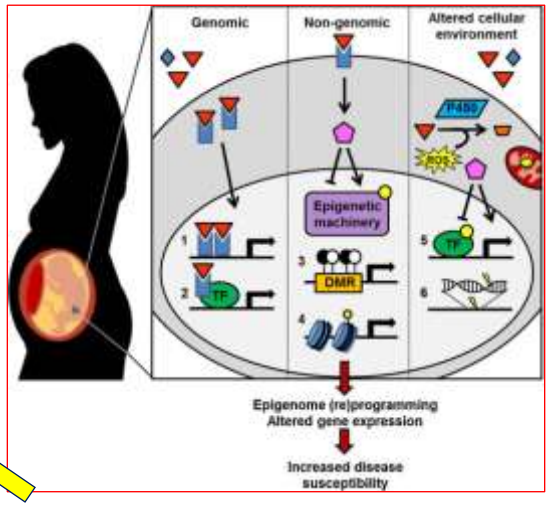


http://www.env-health.org/news/latest-news/article/health-costs-in-the-eu-how-much-is

Question 3

Can we still doubt that **the presence for many years** of **epi-genotoxic molecules** such as ***dioxin*** in Seveso or Taranto and ***chlordecone*** in Martinique and Guadeloupe..

in the **food chains** and **aquifers** of a country and therefore in the organisms of **young people at the age of procreating and in their *gametes*** is a **primary cause of *poor fetal tissue and organ programming*** **and thus of increasing tumors' rates** (especially ***prostate cancer***) and ***neurodevelopmental disorders***?



https://www.sciencedirect.com/science/article/pii/S1084952115001056

- ***Kepone (Chlordecone)*** is an obsolete **insecticide related to Mirex and DDT: Martinique is heavily contaminated, following years of its unrestricted use** in the banana plantations
- It is a known ***Persistent Organic Pollutant (POP),*** classified among the "***dirty dozen***": its use was so disastrous that it is now **banned in the Western World by the Stockholm Convention** on Persistent Organic Pollutants (2011) but only after many millions of kilograms had been produced
- Kepone **bio-accumulates in animals and food-chains by factors up to a million-fold**
- Workers with repeated exposure suffer severe convulsions resulting from degradation of the synaptic junctions.

Financé au titre de: FP5-LIFE QUALITY

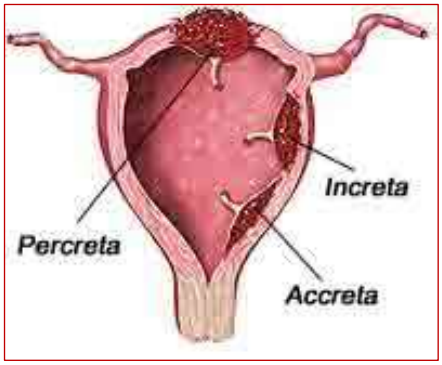
Le placenta transmet les pesticides au fœtus

L'incidence des allergies comme l'asthme a augmenté au cours des dernières décennies. Dans le cadre des efforts menés pour en trouver la raison, les scientifiques ont étudié le transport des composés chimiques à travers le placenta, du milieu environnant vers le fœtus.

This is an **official website of the European Community** that lists many studies related to the problem of **maternal-fetal exposure to pollutants** and **toxics** (in particular to ***pesticides***): scientists found that **all xenobiotics cross the placental barrier by passive diffusion and reach the fetus**..... In the main fetal organs (especially in the blood, spleen, bone marrow, brain and liver) **the concentration of these pesticides is higher than in the corresponding maternal organs**. The implications are of great significance: the **accumulation of these compounds in the fetal tissues will have an impact on the development of the child's immune and nervous systems**

1 In fact **placental alterations** are more and more frequent

The ***placenta accreta*** is an insertion/invasion of/by the placenta **into maternal tissues**: there are three types according to the **insertion depth into the endo/myometrium**
- the proper placenta accreta : the villi penetrate more or less deeply into the myometrium;
- the placenta ***increta***: the villi invade the whole myometrium;
- the placenta ***percreta***: the villi go beyond the myometrium, sometimes **invading neighboring organs (bladder)** ...



... it is, in fact, ***as if the (immunological) mechanisms of maternal-fetal tolerance were weakening !***
... we must not forget that the placenta is largely **an embryo-fetal organ** (that the **embryo** himself produces **to connect** to the mother to get oxygen, nutrition, **information**... certainly not to invade her)

(***evolutionary mechanisms*** that are **millions of years old**)

Choriocarcinoma

2 ... even more common all over the world has become **prematurity (today one child out of 10 is born prematurely** ... which represents **an increase of 30% over the last 35 years** ....) .. **another symptom of growing maternal-fetal intolerance** that should not be underestimated..

L'INSERM today defines different stages of prematurity:
extremely preterm (less than 28 weeks)
very preterm (28 to 32 weeks)
moderate to late preterm (32 to 37 weeks).

Épidémiologie [modifier | modifier le code]

En 2012, plus d'un bébé sur dix naît prématurément dans le monde[5] sans évidence de décroissance avec le temps[6].

Les naissances prématurées concernent 11 à 13 % des naissances aux États-Unis, soit près du double du taux des autres pays industrialisés et une augmentation de 30 % par rapport à 1981[7]. Plus du quart des décès néonataux seraient la conséquence de la prématurité[8].

Les données sont probablement assez solides et permettent d'avoir aujourd'hui un aperçu évolutif concernant les trois dernières décennies en France.

Évolution des taux d'incidence de la prématurité en France

	1972	1981	1988	1995	2003
Très grande prématurité (de 22 à 27 SA)	-	-	-	0,4 %	0,5 %
Grande prématurité (de 28 à 32 SA)	1,3 %	-	1 %	1,2 %	1,3 %
Prématurité (de 33 à 37 SA)	8,2 %	5,7 %	4,8 %	5,9 %	7,2 %

L'incidence est donc en augmentation, ce que confirme les chiffres d'autres pays, en particulier américains[7].

Chlordecone is an organochlorine pesticide that has been widely used ... in the French West Indies. Data from the ***Timoun Mother-Child Cohort Study*** conducted in Guadeloupe between 2004 and 2007 examined **combinations of chlordecone concentrations in maternal plasma with gestational duration and preterm birth rate in 818 pregnant women** ... 1-log10 **increase in chlordecone concentration was associated with decreased duration of pregnancy** (-0.27 weeks, 95% confidence interval: -0.50, -0.03) and **increased risk premature labor** (60%; 130). ... These results are relevant to public health because of the **prolonged persistence of Chlordecone in the environment and the high rate of preterm birth** in this population.

In such a context, the organ that acquires a **truly extraordinary importance is the PLACENTA**: an organ that has been **poorly studied** until a few years ago and that emerges as a sort of **"*Black Box*" for epigenetically programming fetal tissues** and organs

Abstract

Over the past quarter century it has become clear that adult onset chronic diseases like heart disease and type 2 diabetes have their roots in early development. The report by David Barker and colleagues showing an inverse relationship between birthweight and mortality from ischemic heart disease was the first clear-cut demonstration of fetal programming. Because fetal growth depends upon the placental capacity to transport nutrients from maternal blood, it has been a suspected causative agent since the original Barker reports. Epidemiological studies have shown that placental size and shape have powerful associations with offspring disease. More recent studies have shown that maternal phenotypic characteristics, such as body mass index and height, interact with placental size and shape to predict disease with much more precision than does birthweight alone. For example, among people in the Helsinki Birth Cohort, who were born during 1924–1944, the risk for acquiring colorectal cancer increased as the placental surface became longer and more oval. Among people in whom the difference between the length and breadth of the surface exceeded 6 cm, the hazard ratio for the cancer was 2.5 (95% CI 1.2–4.7, p=0.003) compared with those in whom there was no difference. Among Finnish men, the hazard ratio for coronary heart disease was 1.07 (1.02–1.13, P=0.01) per 1% increase in the placental weight/birthweight ratio. Thus, it appears that the ratio of birthweight to placental weight, known as placental efficiency, predicts cardiovascular risk as well. Babies born with placentas at the extremes of efficiency are more vulnerable for adult onset chronic diseases. Recent evidence suggests that placental growth patterns are sex specific. Boys' placentas are, in general, more efficient than those made by girls. Another recent discovery is that the size, shape and efficiencies of the placenta can change over years of time with very narrow confidence limits. This suggests that the growth of the placenta within a population of women is strongly affected by their nutritional environment. Even though it

PROGRAMMA CCM 2017– PROGETTI ESECUTIVI IN ORDINE DECRESCENTE DI PUNTEGGIO DI VALUTAZIONE				
N.	TITOLO	ENTE PARTNER	ID	IMPORTO
1	URBAN HEALTH: BUONE PRATICHE PER LA VALUTAZIONE DI IMPATTO SULLA SALUTE DEGLI INTERVENTI DI RIQUALIFICAZIONE E RIGENERAZIONE URBANA E AMBIENTALE	LOMBARDIA	4	€ 450.000,00
2	SCEGLIERE LE PRIORITÀ DI SALUTE E SELEZIONARE GLI INTERVENTI EFFICACI PER PREVENIRE IL CARICO DELLE MALATTIE CRONICHE NON TRASMISSIBILI	PIEMONTE	6	€ 449.250,00
3	SVILUPPO E VALIDAZIONE DI UN SISTEMA DI MONITORAGGIO EPIDEMIOLOGICO DELLE DEMENZE BASATO SUI DATI DEI SISTEMI INFORMATIVI SANITARI	CAMPANIA	5	€ 450.000,00
4	AMBIENTE, PROGRAMMAZIONE EPIGENETICA FETALE E PREVENZIONE DELLE PATOLOGIE CRONICHE	SARDEGNA	9	€ 448.000,00

For all these reasons we've got **an important funding from the Italian Ministry of Health** for a major project to study the **placentas (especially from Taranto**, the city with the largest iron and steel plant in Europe):

- ***Mass spectrometry*** (IZS - Bologna)
- ***Immunohistochemistry*** (University of Cagliari)
- ***Epigenetics*** (University of Pisa)
- ***Mitochondria*** (University of Milan)
- ***Metabolomics*** (University of Cagliari)
- ***follow-up* of children at risk by the *Italian Federation of Pediatricians* (*FIMP*): - early diagnosis !! - personalized treatment !!**

But **most importantly**, it is becoming increasingly obvious that **the most serious consequences of the increasing embryo-foetal exposure to toxics will become evident after decades** (and sometimes only in the **following generations**)

Conséquences à long terme

Les données de l'étude épidémiologique française ÉPIPAGE sur les petits âges gestationnels permettent de déceler un lien évident entre la survenue d'un handicap et l'importanc de la prématurité. Près de 40 % des grands prématurés présentent des séquelles - troubles moteurs, sensoriels ou cognitifs - à l'âge de 5 ans, sévères dans 5 % des cas, modérées pour 9 % des enfants, légères pour les autres[22]. Ces données sont cohérentes avec celles issues d'autres études d'autres pays[23].

The Barker Hypothesis
Fetal Origins of Adult Disease

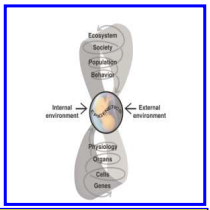
Adverse intrauterine events permanently "program" postnatal structure/function/homeostasis

"Adapted Birth Phenotype"

- Better chance of fetal survival
- Increased risk of adult disease

.. since every intrauterine adverse events might **interfere permanently with the epigenetic programming** of organs and tissues (***DOHaD theory***)

The 7 keywords: from genetics to *epigenetics*



3

Fetal programming

2

Environment

The ***environment*** should be considered as a **continuous flow of information** coming from outside and reaching the epigenome, **causing it to activate and to continuously change** its molecular **three-dimensional structure** (Chromatin)

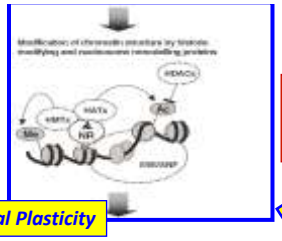
1

From Genetics to Epigenetics

Ontogeny*

4

Developmental Plasticity



Phylogeny*

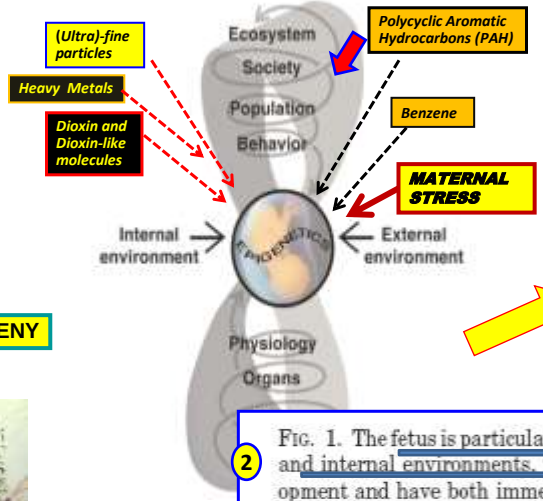
The **third** key word is ***fetal programming ...***



ONTOGENY

… a technical term that refers to the ***capability*** and, at the same time, the ***requirement***, for **embryo-foetal cells to define their epigenetic setting in a predictive and adaptive way** , in relation to the information coming from the mother and, through her, from the outer world ..

A ***predictive adaptive response (PAR)*** is a developmental trajectory taken by an organism during a period of ***developmental plasticity*** in response to perceived environmental cues..

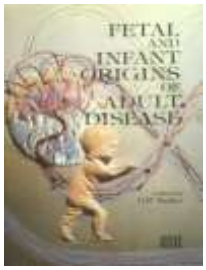


FIG. 1. The fetus is particularly vulnerable to changes in the external and internal environments, which interact to influence fetal development and have both immediate and life-long consequences. Such environmentally induced changes can occur at all levels of biological organization, from the molecular to the organism's behavior and place in society, and tend to be amplified in their consequences as they ascend through these levels. Ultimately, these influences may be epigenetic in nature, inducing mitotically heritable alterations in gene expression without changing the DNA.

The **fourth** keyword is ***developmental plasticity***

Cellular Differentiation*: an *epigentic process

The actual genetic program of a single multicellular organism is the product of nine months of epigenetic adaptive-predictive "formatting" of trillions of cells)

1 ⇩ 2

Differentiation is the process through wich the organism changes **from a zygote to a complex system** of **tissues** and **200 cell types (genetically identical.. each with its own epigenetic and morpho-functional characteristics) ..**

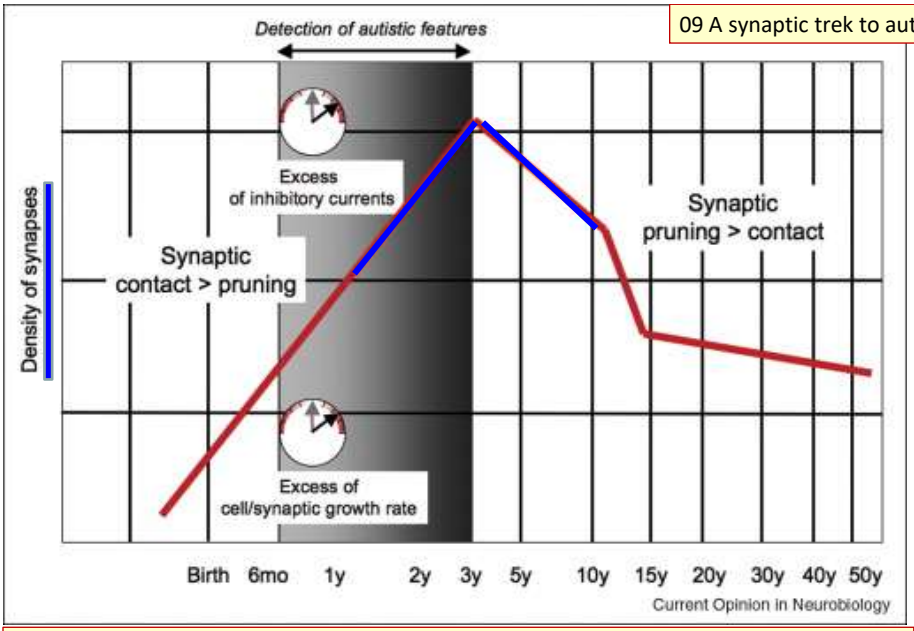
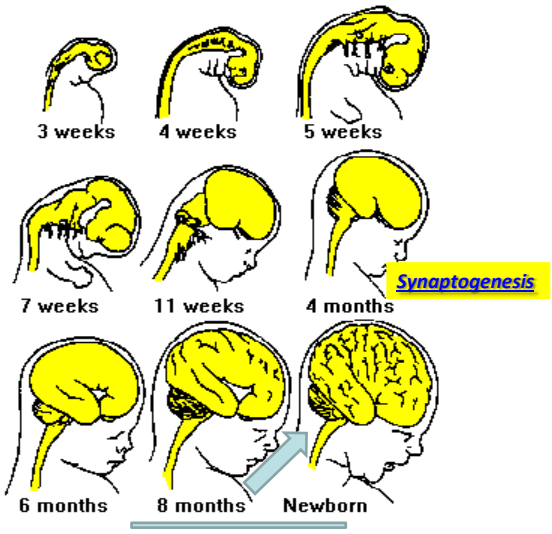
09 A synaptic trek to autism



Schematic representation of the **different phases of synaptogenesis** in the human brain. **During the first three years of life, an excess of cell/synaptic growth rate and inhibitory currents could increase the risk of ASD.**



Synaptogenesis

The brain grows at an amazing rate during development.
At times during brain development, **250,000 neurons are added every minute!**
At birth, almost all the neurons that the brain will ever have are present.

However, the brain continues to grow for many years after birth.

By the age of 2 years old, the brain is about **80% of the adult size**

A **stegosaurus dinosaur weighed approximately 1,600 kg but had a brain that weighed only approximately 70 grams (0.07 kg).** Therefore, **the brain was only 0.004% of its total body** weight. In contrast, an adult human weighs approximately 70 kg and has a brain that weighs approximately 1.4 kg. Therefore, **the human brain is about 2% of the total body weight**. This makes the brain to body ratio of the human **500 times greater than that of the stegosaurus**

Review

Maternal Factors that Induce Epigenetic Changes Contribute to Neurological Disorders in Offspring

Avijit Banik [1], Deepika Kandilya [1], Seshadri Ramya [1], Walter Stünkel [2], Yap Seng Chong [3] and S. Thameem Dheen [1,*]

It is well established that **the regulation of epigenetic factors**, including **chromatin reorganization, histone modifications, DNA methylation, and miRNA regulation, is critical for the normal development and functioning of the human brain**.
There are a number of **maternal factors influencing epigenetic pathways** such as **lifestyle, including diet, alcohol consumption, and smoking**, as well as **age and infections** (viral or bacterial).

Genetic and metabolic alterations such as **obesity, gestational diabetes mellitus (GDM), and thyroidism alter epigenetic mechanisms, thereby contributing to neurodevelopmental disorders (NDs) such as embryonic neural tube defects (NTDs), autism, Down's syndrome, Rett syndrome, and later onset of neuropsychological deficits**.

This review comprehensively describes the recent findings in the epigenetic landscape contributing to altered molecular profiles resulting in NDs. Furthermore, we will discuss potential avenues for future **research to identify diagnostic markers and therapeutic epi-drugs to reverse these abnormalities in the brain as epigenetic marks are plastic and reversible in nature.**

Figure 1 Smoking in mothers alters neurodevelopmental processes in the fetus. Maternal smoking alters the DNA methylation of genes involved in placental and fetal development, leading to neurodevelopmental disorders in the offspring.

Maternal Smoking

Phenotypic outcomes in the offspring

Fetal alcohol spectrum disorder (FASD)

- Attention and memory deficit
- Craniofacial malformation
- Motor function abnormalities
- Auditory and language problem

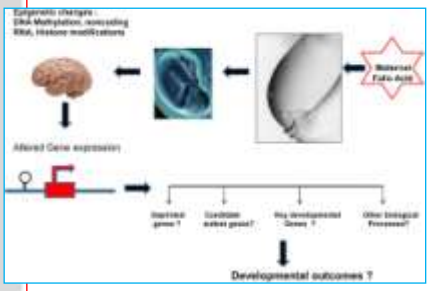
F3 Effect of **maternal dietary deficiency** on fetal development.
The absence of essential dietary supplements in maternal diet during gestation leads to a disruption in metabolic pathways and several epigenetic alterations in the fetus, triggering **abnormal uterine development** and **neurodevelopmental disorders**.

Maternal dietary deficiency

Absence of dietary methyl group donors such as folate, choline, methionine, betain and methylcobalamine

- Imbalance in folate-mediated one-carbon metabolism (FOCM) pathway [98]
- Mutation in methionine synthase reductase (*Mtrr*) gene, essential for deployment of methyl groups from the folate cycle [104]
- Down-regulation of genes related to fetal brain development: *BDNF*, *CREB*, *NGF* and *TrkB* [105]
- H3K9 and H4K20 methylation [114]
- Altered expression of miRNAs linked to FOCM pathway : miR-29c, miR-183, miR-422b, miR-189 [115]; miR-22, miR-24, miR-29b, miR-34a, miR-125, miR-344-5p/484, miR-488 [116-118]

Abnormal uterine development and congenital malformation [104]



F4 Effect of **maternal metabolic conditions** on fetal development.
Metabolic conditions at gestation such as GDM, obesity, and hypothyroidism induce epigenetic alterations in the fetus, leading to a series of **metabolic and immunogenic changes triggering neuroanatomical and neuropsychological deficits in the developing brain**.

Maternal metabolic conditions

- Gestational Diabetes Mellitus (GDM)
- Maternal Obesity
- Maternal Hypothyroidism

Trigger epigenetic imbalance in the fetus [149,150,157,158,172]

- Induces oxidative stress [148]
- ROS accumulation [148]
- Inflammatory response [155]
- Cytokine production [156]
- Decreased T3 levels [169]
- Altered levels of metabolic genes [172]

Neuroanatomical /neuropsychological deficits in developing brain

Possible mechanisms mediating the pathological effects of maternal infection on the developing organism in utero

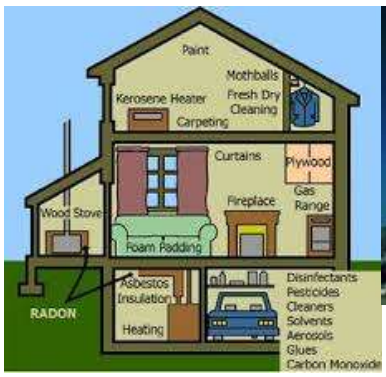
Children whose mothers smoke:

- **70%** more respiratory problems
- Pneumonia and hospitalization in year 1 is **38%** higher
- Infant mortality is **80%** higher
- **20%** of all infant deaths could be avoided if all pregnant smokers stopped by the 16th week of gestation

Environmental tobacco smoke (ETS)

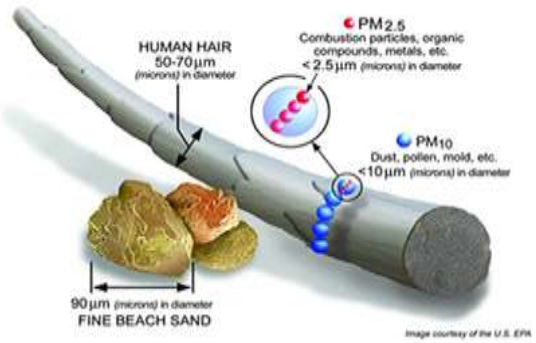
- Sudden infant death syndrome
- Lower respiratory tract illness
- Middle ear disease
- Asthma
- 12 million children exposed to secondhand smoke in homes

- Exposure to environmental tobacco smoke (ETS) causes more than 35,000 deaths annually among non-smokers.
- Smoking by pregnant women is responsible for about 1000 infant deaths each year in the U.S.
- Children exposed to ETS suffer higher rates of asthma, bronchitis, and pneumonia.
- Smokeless tobacco use has tripled since 1972, and cigar use has increased 50% since 1993.



House dust mites

- House dust mites produce *Der p I* allergen, a potent sensitizer
- Good evidence of increased risk of sensitization with increasing allergen exposure, but this does not necessarily lead to asthma
- Small reductions in exposure will not necessarily lead to reduced incidence and/or symptoms
- Indoor humidity is important



Living near a freeway, based on the location of the birth, and third trimester address, and **autism**

PM2.5, PM10, and NO2 at residences were higher in children with autism.

UPs pass easily through the olfactory nerve and the BBB into the brain

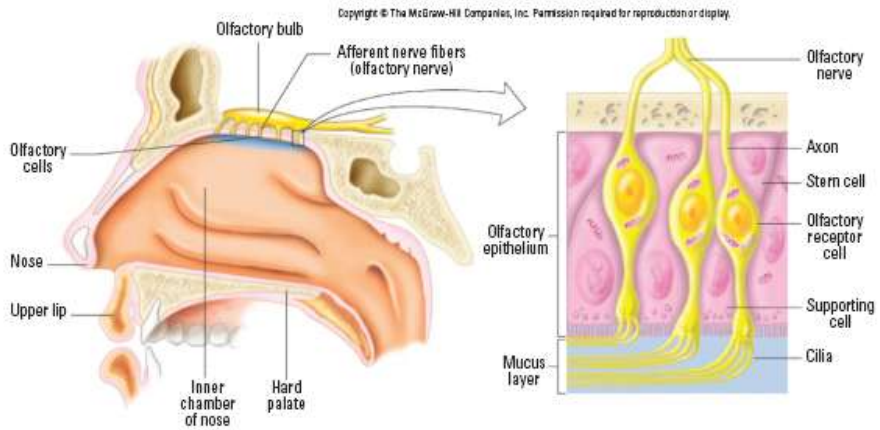

Figure 12. Close proximity of olfactory mucosa to olfactory bulb of the CNS. Inhaled NSP[s], especially below 10 nm, deposit efficiently on the olfactory mucosa by diffusion, similar to airborne "smell" molecules which deposit in this area of olfactory dendritic cilia. Subsequent uptake and translocation of solid NSP[s] along axons of the olfactory nerve has been demonstrated in non-human primates and rodents. Surface chemistry of the particles may influence their neuronal translocation. Copyright © the McGraw-Hill Companies, Inc. Reproduced from Widmaier et al. (2004) with permission from McGraw-Hill.

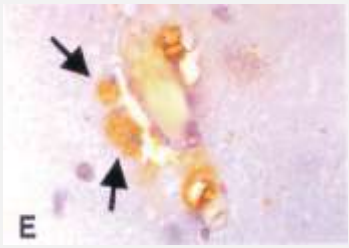
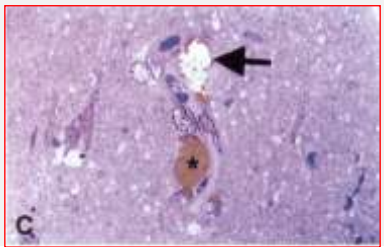
Toxicol Pathol 2002; 30: 373
DOI: 10.1080/01926230252929954

Exposure to complex mixtures of air pollutants produces inflammation in the upper and lower respiratory tract. Because the nasal cavity is a common portal of entry, respiratory and olfactory epithelia are vulnerable targets for toxicological damage. This study has evaluated, by light and electron microscopy and immunohistochemical expression of nuclear factor-kappa beta (NF-κB) and inducible nitric oxide synthase (iNOS), the olfactory and respiratory nasal mucosae, olfactory bulb, and cortical and subcortical structures from 32 healthy mongrel canine residents in Southwest Metropolitan Mexico City (SWMMC), a highly polluted urban region. Findings were compared to those in 8 dogs from Tlaxcala, a less polluted, control city. In SWMMC dogs, expression of nuclear neuronal NF-κB and iNOS in cortical endothelial cells occurred at ages 2 and 4 weeks; subsequent damage included alterations of the blood–brain barrier (BBB), degenerating cortical neurons, apoptotic glial white matter cells, deposition of apolipoprotein E (apoE)-positive lipid droplets in smooth muscle cells and pericytes, nonneuritic plaques, and neurofibrillary tangles. Persistent pulmonary inflammation and deteriorating olfactory and respiratory barriers may play a role in the neuropathology observed in the brains of these highly exposed canines. Neurodegenerative disorders such as Alzheimer's may begin early in life with air pollutants playing a crucial role.





And **a similar condition has been documented in the brain of young people dead for accidental causes..**

Pediatric Respiratory and Systemic Effects of Chronic Air Pollution Exposure: Nose, Lung, Heart, and Brain Pathology

Lilian Calderón-Garcidueñas, Maricela Franco-Lira, Ricardo Torres-Jardón, Carlos Henriquez-Roldán, Gerardo Barragán-Mejía, Gildardo Valencia-Salazar, Angelica González-Maciel, Rafael Reynoso-Robles, Rafael Villarreal-Calderón and William Reed

Toxicol Pathol 2007; 35: 154

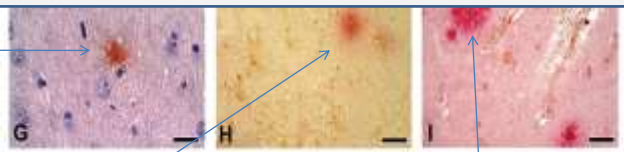
Exposures to **particulate matter and gaseous air pollutants** have been associated with **respiratory tract inflammation**, disruption of the nasal respiratory and olfactory barriers, **systemic inflammation**, production of mediators of inflammation capable of **reaching the brain and systemic circulation of particulate matter**. Mexico City (MC) residents are exposed to significant amounts of ***ozone, particulate matter*** and associated *lipopolysaccharides*. **MC dogs** exhibit brain inflammation and an acceleration of **Alzheimer's-like pathology, suggesting that the brain is adversely affected by air pollutants**.

MC children, adolescents and adults have a significant **upregulation of cyclooxygenase-2 (COX2) and interleukin-1*β* (IL-1*β*) in olfactory bulb and frontal cortex**, as well as **neuronal and astrocytic accumulation of the 42 amino acid form of *β*-amyloid peptide (A*β*42), including diffuse amyloid plaques in frontal cortex**.

The pathogenesis of Alzheimer's disease (AD) is characterized by brain inflammation and the accumulation of A*β*42, which precede the appearance of neuritic plaques and neurofibrillary tangles, the pathological hallmarks of AD.

Our findings of nasal barrier disruption, systemic inflammation, and the upregulation of COX2 and IL-1*β* expression and A*β*42 accumulation in brain suggests that sustained exposures to significant concentrations of air pollutants such as particulate matter could be a risk factor for AD and other neurodegenerative diseases.

The frontal cortex of an 11-month-old healthy MC dog exhibits **A*β*42** *staining of a* ***diffuse plaque****, surrounded by a microglia-like nucleus*



The frontal cortex of a **17-year-old MC boy**… shows **a diffuse *Aβ42 plaque*** *(red product) and GFAP-negative astrocytes*

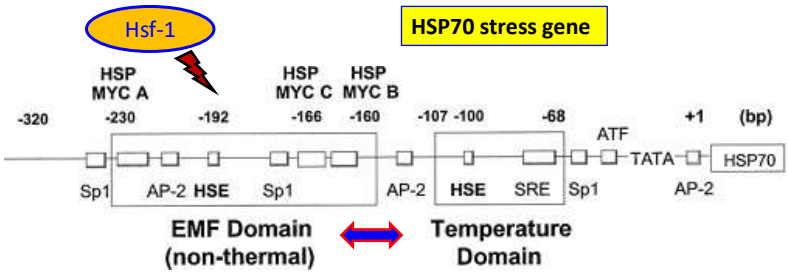
Electromagnetic Fields, Pulsed Radiofrequency Radiation, and Epigenetics: How Wireless Technologies May Affect Childhood Development

Cindy Sage
Sage Associates

Ernesto Burgio
International Society of Doctors for Environment (ISDE) Scientific Office

Mobile phones and other wireless devices that produce electromagnetic fields (EMF) and pulsed radiofrequency radiation (RFR) are widely documented to cause potentially harmful health impacts that can be detrimental to young people. New epigenetic studies are profiled in this review to account for some neurodevelopmental and neurobehavioral changes due to exposure to wireless technologies. Symptoms of retarded memory, learning, cognition, attention, and behavioral problems have been reported in numerous studies and are similarly manifested in autism and attention deficit hyperactivity disorders, as a result of EMF and RFR exposures where both epigenetic drivers and genetic (DNA) damage are likely contributors. Technology benefits can be realized by adopting wired devices for education to avoid health risk and promote academic achievement.

Specific DNA sequences on the promoter of the HSP70 stress gene are responsive to EMF...



Synthesis of this stress protein is initiated in a **region of the promoter** where a transcription factor known as **Heat Shock Factor 1 (HSF-1) binds to a Heat Shock Element (HSE).**
The **EMF sensitive region on HSP70 promoter** is **upstream from the thermal domain of the promoter and is not sensitive to increased temperature**. The binding of **HSF-1** to **HSE** occurs at **–192** in the **HSP70 promoter** relative to the transcription initiation site.

The **EMF domain contains three nCTCTn myc-binding sites –230, –166 and –160 relative to the transcription initiation site and upstream of the binding sites for the heat shock (nGAAn**) and serum responsive elements…. **The electromagnetic response elements (EMREs) have also been identified on the c-*myc* promoter and are also responsive to EMF**

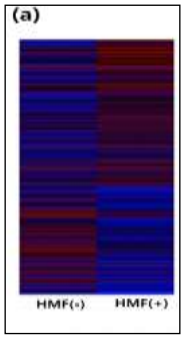
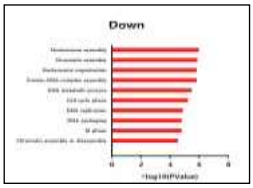
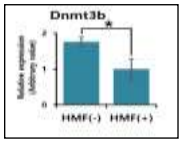
Effects of a hypomagnetic field on DNA methylation during the differentiation of embryonic stem cells

Soonbong Baek[1], Hwan Choi[2], Hanseul Park[2], Byunguk Cho[1], Siyoung Kim[3] & Jongpil Kim[1,2]

It has been reported that hypomagnetic fields (HMFs) have a negative influence on mammalian physiological functions. We previously reported that HMFs were detrimental to cell fate changes during reprogramming into pluripotency. These studies led us to investigate whether HMFs affect cell fate determination during direct differentiation. Here, we found that an HMF environment attenuates differentiation capacity and is detrimental to cell fate changes during the in vitro differentiation of embryonic stem cells (ESCs). Moreover, HMF conditions cause abnormal DNA methylation through the dysregulation of DNA methyltransferase3b (Dnmt3b) expression, eventually resulting in incomplete DNA methylation during differentiation. Taken together, these results suggest that an appropriate electromagnetic field (EMF) environment may be essential for favorable epigenetic remodeling during cell fate determination via differentiation.







…campi ipomagnetici (HMF) influenzano la determinazione del destino cellulare… interferendo sulla **differenziazione in vitro delle cellule staminali embrionali (ESC).**

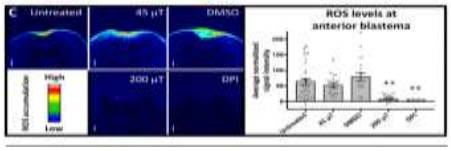
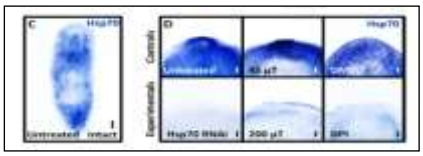
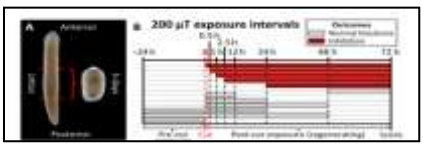
Weak magnetic fields alter stem cell–mediated growth

Alanna V. Van Huizen[1], Jacob M. Morton[1], Luke J. Kinsey[1], Donald G. Von Kannon[1], Marwa A. Saad[1], Taylor R. Birkholz[1], Jordan M. Czajka[1], Julian Cyrus[2], Frank S. Barnes[2], Wendy S. Beane[1]*

Biological systems are constantly exposed to electromagnetic fields (EMFs) in the form of natural geomagnetic fields and EMFs emitted from technology. While strong magnetic fields are known to change chemical reaction rates and free radical concentrations, the debate remains about whether static weak magnetic fields (WMFs; <1 mT) also produce biological effects. Using the planarian regeneration model, we show that WMFs altered stem cell proliferation and subsequent differentiation via changes in reactive oxygen species (ROS) accumulation and downstream heat shock protein 70 (Hsp70) expression. These data reveal that on the basis of field strength, WMF exposure can increase or decrease new tissue formation in vivo, suggesting WMFs as a potential therapeutic tool to manipulate mitotic activity.







Campi magnetici statici deboli (WMF <1 mT) producono **alterazioni della proliferazione delle cellule staminali e della successiva differenziazione** attraverso cambiamenti nell'**accumulo di specie reattive dell'ossigeno (ROS)** e nell'**espressione della proteina di shock termico 70 (Hsp70)**.

Questi dati rivelano che sulla base della forza del campo, l'esposizione al WMF può aumentare o diminuire la **formazione di nuovo tessuto *in vivo*...**

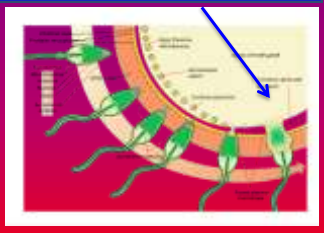
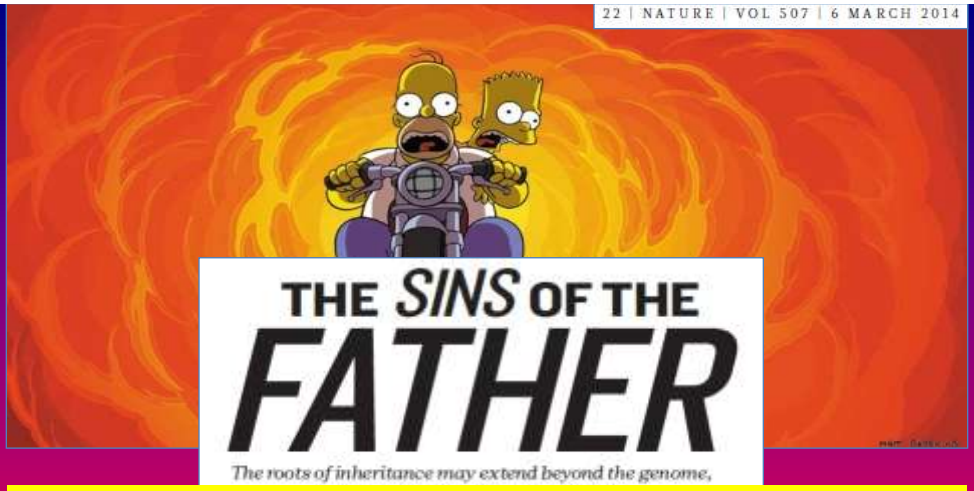
The overlooked heritage: the genetic transmission by the father

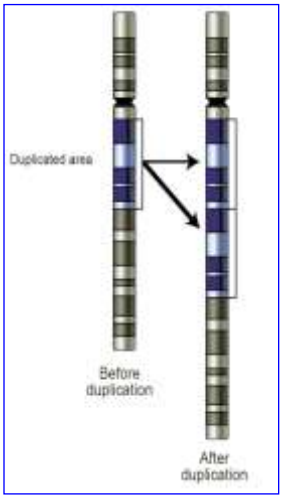


ERNESTO BURGIO
ECERI - European Cancer and Environment Research Institute
ISDE Scientific Committee



When Brian Dias became a father last October, he was, like any new parent, **mindful of the enormous responsibility** that lay before him... But, unlike most new parents, **Dias was also aware of the influence of his past experiences — not to mention those of his parents, his grandparents and beyond, whether they smoked, endured famine or fought in a war.** As a postdoc he had spent much of the two years before studying these kinds of questions in mice: **specifically, he looked at how fear associated with a particular smell affects the animals and leaves an imprint on the brains of their descendants.**

What is most striking is that the same CNVs have been found, at least in some cases, in the semen of parents, showing that autism could be the consequence of a parental exposure to pollutants and a transgenerational transmission: which could provide **an explanation for the unremitting "pandemic" increase of these disorders.**



All that said .. it **is absolutely necessary to reconsider the problem of many early environmental exposures or even gametic, and their possible synergy .. which can induce an epigenetic instability,**

Strong Association of De Novo Copy Number Mutations with Autism
Jonathan Sebat *et al.*
Science **316**, 445 (2007);

Science
AAAS

We tested the hypothesis that de novo copy number variation (CNV) is associated with autism spectrum disorders (ASDs). We performed comparative genomic hybridization (CGH) on the genomic DNA of patients and unaffected subjects to detect copy number variants not present in their respective parents. Candidate genomic regions were validated by higher-resolution CGH, paternity testing, cytogenetics, fluorescence in situ hybridization, and microsatellite genotyping. Confirmed de novo CNVs were significantly associated with autism ($P = 0.0005$). Such CNVs were identified in 12 out of 118 (10%) of patients with sporadic autism, in 2 out of 77 (3%) of patients with an affected first-degree relative, and in 2 out of 196 (1%) of controls. Most de novo CNVs were smaller than microscopic resolution. Affected genomic regions were highly heterogeneous and included mutations of single genes. These findings establish de novo germline mutation as a more significant risk factor for ASD than previously recognized.

Rare Structural Variants Disrupt Multiple Genes in Neurodevelopmental Pathways in Schizophrenia

Tom Walsh *et al.*

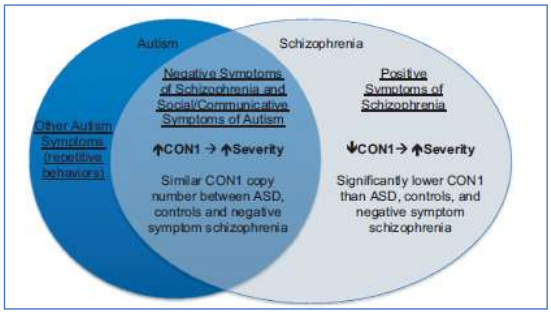
Science **320**, 539 (2008);

Science

AAAS

Schizophrenia is a devastating neurodevelopmental disorder whose genetic influences remain elusive. We hypothesize that individually rare structural variants contribute to the illness. Microdeletions and microduplications >100 kilobases were identified by microarray comparative genomic hybridization of genomic DNA from 150 individuals with schizophrenia and 268 ancestry-matched controls. All variants were validated by high-resolution platforms. Novel deletions and duplications of genes were present in 5% of controls versus 15% of cases and 20% of young-onset cases, both highly significant differences. The association was independently replicated in patients with childhood-onset schizophrenia as compared with their parents. Mutations in cases disrupted genes disproportionately from signaling networks controlling neurodevelopment, including neuregulin and glutamate pathways. These results suggest that multiple, individually rare mutations altering genes in neurodevelopmental pathways contribute to schizophrenia.

DUF1220 CNVs.. Neural stem cells proliferation.. Human Brain Evolution.. Autism & Schizofrenia



DUF1220 copy number associations support autism and schizophrenia being related disorders. CON1 associations with negative symptoms in schizophrenic males, and with social/ communicative symptoms in ASD, suggest these phenotypes overlap between the disorders. The inverse association between CON1 and positive symptoms suggest that positive symptoms could be considered as an opposing phenotype to ASD. ASD, autism spectrum disorder.

DUF1220 protein domains drive proliferation in human neural stem cells and are associated with increased cortical volume in anthropoid primates

Epigenetic regulation of the glucocorticoid receptor in human brain associates with childhood abuse

nature neuroscience

Patrick O McGowan[1,2], Aya Sasaki[1,2], Ana C D'Alessio[3], Sergiy Dymov[3], Benoit Labonté[1,4], Moshe Szyf[2,3], Gustavo Turecki[1,4] & Michael J Meaney[1,2,5]

VOLUME 12 | NUMBER 3 | MARCH 2009 NATURE NEUROSCIENCE

Maternal care influences hypothalamic-pituitary-adrenal (HPA) function in the rat through epigenetic programming of glucocorticoid receptor expression. In humans, childhood abuse alters HPA stress responses and increases the risk of suicide. We examined epigenetic differences in a neuron-specific glucocorticoid receptor (*NR3C1*) promoter between postmortem hippocampus obtained from suicide victims with a history of childhood abuse and those from either suicide victims with no childhood abuse or controls. We found decreased levels of glucocorticoid receptor mRNA, as well as mRNA transcripts bearing th glucocorticoid receptor 1_F splice variant and increased cytosine methylation of an *NR3C1* promoter. Patch-methylated *NR3C1* promoter constructs that mimicked the methylation state in samples from abused suicide victims showed decreased NGFI-A transcription factor binding and NGFI-A–inducible gene transcription. These findings translate previous results from rat to human and suggest a common effect of parental care on the epigenetic regulation of hippocampal glucocorticoid receptor expression.

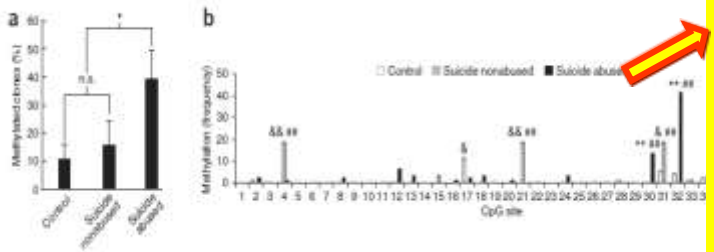

Figure 2 Methylation of the *NR3C1* promoter in the hippocampus. Twenty clones were sequenced for each subject for methylation mapc percentage of methylated clones for suicide victims with a history of childhood abuse ($n = 12$), suicide victims without a history of child and controls ($n = 12$). The methylation percentage was calculated as the number of clones with at least one methylated CpG site divide number of clones (* indicates $P < 0.05$; n.s. indicates not statistically significant). (b) Methylation of the *NR3C1* promoter region, show of methylation observed at each CpG site for suicide victims with a history of childhood abuse, suicide victims with no history of childho control subjects (*$P < 0.05$, **$P < 0.001$, abused suicides versus controls; $^{\S}P < 0.05$, $^{\S\S}P < 0.001$, non-abused suicides versus co $^{\#\#}P < 0.001$, abused suicides versus non-abused suicides; Bonferroni *post hoc* comparisons).

Maternal care influences the programming of the hypothalamic-pituitary-adrenal Axis (**HPA**) through epigenetic programming of ***glucocorticoid receptors expression***...

We found a **greatly increased methylation of cytosine in the promoter of a gene** codifying for a Glucocorticoids-Neuro-Receptor (NR3C1) **in the hippocampus of suicide victims with a history of childhood abuse** .. (post-mortem examinations)

Association of Maternal Exposure to Childhood Abuse With Elevated Risk for Autism in Offspring

Andrea L. Roberts, PhD; Kristen Lyall, ScD; Janet W. Rich-Edwards, ScD; Alberto Ascherio, DrPH; Marc G. Weisskopf, PhD, ScD

JAMA Psychiatry. 2013;70(5):508-515. Published online March 20, 2013. doi:10.1001/jamapsychiatry.2013.447

Importance: Adverse perinatal circumstances have been associated with increased risk for autism in offspring. Women exposed to childhood abuse experience more adverse perinatal circumstances than women unexposed, but whether maternal abuse is associated with autism in offspring is unknown.

Design and Setting: Nurses' Health Study II, a population-based longitudinal cohort of 116 430 women.

Conclusions and Relevance: We identify an intergenerational association between maternal exposure to childhood abuse and risk for autism in the subsequent generation. Adverse perinatal circumstances accounted for only a small portion of this increased risk.

Another **transgenerational effect**, is based **on a broad longitudinal cohort study *(Nurses' Health Study II*** which **identified maternal exposure to abuse in early childhood (!!)** as a risk factor for having a child with autism **e (Nurses 'Health Study II)**

Epigenetic Transmission of Holocaust Trauma: Can Nightmares Be Inherited?

Natan P.F. Kellermann

AMCHA, the National Israeli Center for Psychosocial Support of Survivors of the Holocaust and the Second Generation, Jerusalem, Israel

The Holocaust left its visible and invisible marks not only on the survivors, but also on their children. Instead of numbers tattooed on their forearms, however, they may have been marked epigenetically with a chemical coating upon their chromosomes, which would represent a kind of biological memory of what the parents experienced. As a result, some suffer from a general vulnerability to stress while others are more resilient. Previous research assumed that such transmission was caused by environmental factors, such as the parents' child-rearing behavior. New research, however, indicates that these transgenerational effects may have been also (epi) genetically transmitted to their children. Integrating both hereditary and environmental factors, epigenetics adds a new and more comprehensive psychobiological dimension to the explanation of transgenerational transmission of trauma. Specifically, epigenetics may explain why latent transmission becomes manifest under stress. A general theoretical overview of epigenetics and its relevance to research on trauma transmission is presented.

The **Holocaust** left its **visible and invisible marks** not only on the survivors, but also on their **children**. Instead of **numbers tattooed on their forearms**, however, they may have been **marked epigenetically with a chemical coating upon their chromosomes**, which would represent a kind of biological memory of what the parents experienced.

Implication of sperm RNAs in transgenerational inheritance of the effects of early trauma in mice

Katharina Gapp[1], Ali Jawaid[1], Peter Sarkies[2], Johannes Bohacek[1], Pawel Pelczar[3], Julien Prados[4,5], Laurent Farinelli[4], Eric Miska[2] & Isabelle M Mansuy[1]

Small non-coding RNAs (sncRNAs) are potential vectors at the interface between genes and environment. We found that traumatic stress in early life altered mouse microRNA (miRNA) expression, and behavioral and metabolic responses in the progeny. Injection of sperm RNAs from traumatized males into fertilized wild-type oocytes reproduced the behavioral and metabolic alterations in the resulting offspring.

Isabelle Mansuy..**periodically separated mother mice from their young pups and exposed the mothers to stressful situations** — either by placing them in cold water or physically restraining them. These separations occurred every day but at erratic times, **so that the mothers could not comfort their pups**

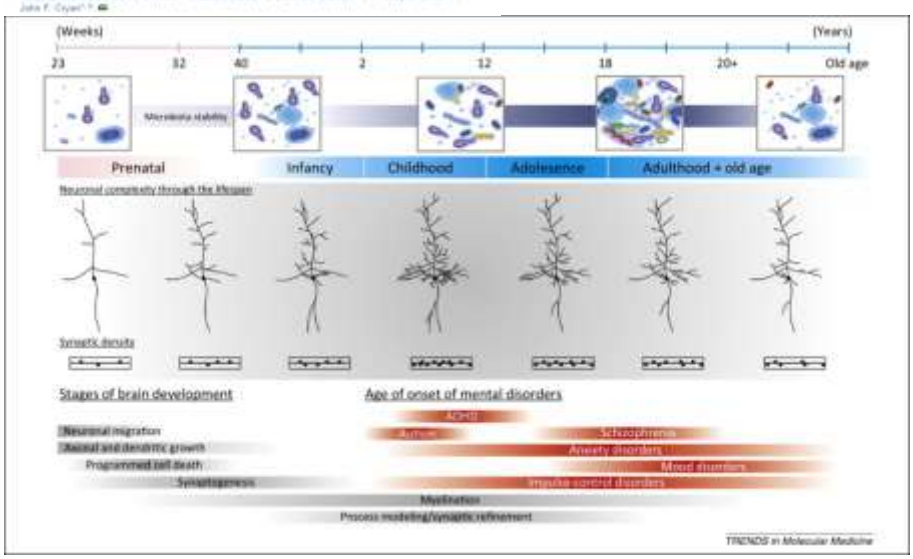
When raised this way, **male offspring showed depressive behaviours and tended to underestimate risk**, the study found. Their **sperm also showed abnormally high expression of five microRNAs**. One of these, **miR-375, has been linked to stress and regulation of metabolism.**

The F1 males' offspring, the F2 generation, showed similar depressive behaviours, as well as abnormal sugar metabolism. The F1 and F2 generations also had **abnormal levels of the five microRNAs in their blood and in the hippocampus**, a brain region involved in stress responses. **Behavioural effects persisted in the F3 generation as well.**

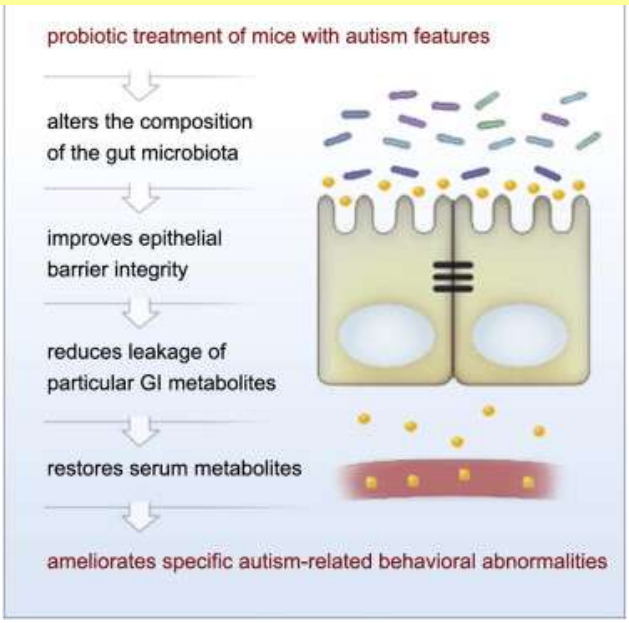
The researchers also collected **RNA from the F1 males' sperm and injected it into freshly fertilized eggs from untraumatized mice**. This resulted in mice with comparable depressive behaviours and metabolic symptoms — and **the depressive behaviours were passed, in turn, to the next generation**.

Remarkably, **offspring from both paternal stress groups displayed significantly reduced HPA stress axis responsivity**…In examining **epigenetic mechanisms of germ cell transmission, we found robust changes in sperm microRNA (miR)..**

Early life perturbations of the developing gut microbiota can **impact neurodevelopment** and potentially lead to **adverse mental health outcomes later in life**



Microbiota Modulate Behavioral and Physiological Abnormalities Associated with Neurodevelopmental Disorders



The normal development of the brain may also depend on microorganisms. The gut microbiota produces about 30% of the metabolites in mammalian circulation, including many neurotransmitters such as γ-aminobutyric acid (GABA), serotonin, histamine and dopamine.

Consistent with this, **in germ-free mice, dopamine and glutamate receptor expression as well as serotonin levels are significantly altered in the circulation during brain development compared with conventional mice**.

This establishes **the gut microbiota–brain axis as an essential regulator of neurodevelopment..** Indeed, **the microbiota may be crucial in shaping host behaviours across many animal taxa, from fruitflies to humans and mice**

Germ-free mice exhibit behaviours of social avoidance, self-grooming, and other traits similar to those observed in disorders of neurodevelopment such as autism spectrum disorder (ASD).

Microbiota Transfer Therapy alters gut ecosystem and improves gastrointestinal and autism symptoms: an open-label study

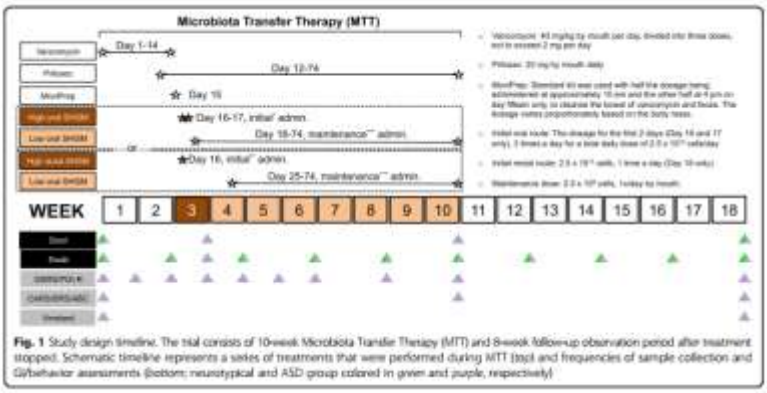

Fig. 1 Study design timeline. The trial consists of 10-week Microbiota Transfer Therapy (MTT) and 8-week follow-up observation period after treatment stopped. Schematic timeline represents a series of treatments that were performed during MTT (top) and frequencies of sample collection and GI/behavior assessments (bottom; neurotypical and ASD group colored in green and purple, respectively)

MTT involved a 2-week antibiotic treatment, a bowel cleanse, and then an extended fecal microbiota transplant (FMT) using a high initial dose followed by daily and lower maintenance doses for 7–8 weeks.

The Gastrointestinal Symptom Rating Scale revealed an approximately **80% reduction of GI symptoms at the end of treatment, including significant improvements in symptoms of constipation, diarrhea, indigestion, and abdominalpain. Improvements persisted 8 weeks after treatment.**

Similarly, clinical assessments showed that behavioral ASD symptoms improved significantly and remained improved 8 weeks after treatment ended.

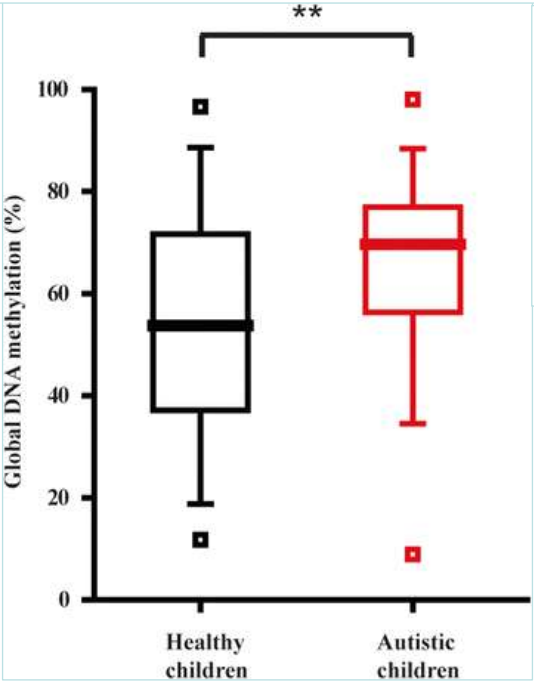
Markers clinici

Variation of global DNA methylation in autistic children.



The *box plot* shows methylation levels in healthy children (*black*) and autistic children (*red*). ..

Here, we have demonstrated that **the global methylation in autistic children was increased compared to healthy children...**

Moreover, in comparison with the time profile for methylation, **the higher methylation level is that expected of young to middle-aged adults and this could be interpreted to suggest an abnormally advanced methylome in autistic children**.

This is reflected in that **no significant difference in methylation was found between autistic children and their parents**.

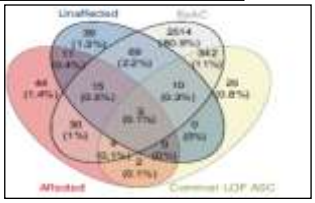
Recessive gene disruptions in autism spectrum disorder

Nat ure Genetics | VOL 51 1092 | JULY 2019 | 1092–1098 | www.nature.com/naturegenetics

Autism spectrum disorder (ASD) affects up to 1 in 59 individuals[1]. Genome-wide association and large-scale sequencing studies strongly implicate both common variants[2–4] and rare de novo variants[5–10] in ASD. Recessive mutations have also been implicated[11–16] but their contribution remains less well defined. Here we demonstrate an excess of biallelic loss-of-function and damaging missense mutations in a large ASD cohort, corresponding to approximately 5% of total cases, including 10% of females, consistent with a female protective effect. We document biallelic disruption of known or emerging recessive neurodevelopmental genes (*CA2, DDHD1, NSUN2, PAH, RARB, ROGDI, SLC1A1, USH2A*) as well as other genes not previously implicated in ASD including *FEV* (FEV transcription factor, ETS family member), which encodes a key regulator of the serotonergic circuitry. Our data refine estimates of the contribution of recessive mutation to ASD and suggest new paths for illuminating previously unknown biological pathways responsible for this condition.



Documentiamo un eccesso di **mutazioni dannose (missenso e con perdita biallelica di-funzione)** in un'ampia coorte ASD, presenti **nel 5% del totale dei casi (10% nelle femmine,** coerentemente con un effetto protettivo del sesso femminile). Documentiamo **mutazioni bialleliche di geni noti o emergenti recessivi implicati nel neurosviluppo (CA2, DDHD1, NSUN2, PAH, RARB, ROGDI, SLC1A1, USH2A)** e di altri geni non precedentemente implicati, incluso **FEV (fattore di trascrizione, membro della famiglia ETS),** che codifica per una proteina che ha un ruolo di regolazione nei **circuiti serotoninergici**. I nostri dati perfezionano le stime del **contributo di mutazioni recessive in ASDs** e suggeriscono nuovi percorsi per illuminare le *pathways* neuro-biologiche implicate e tuttora ignote

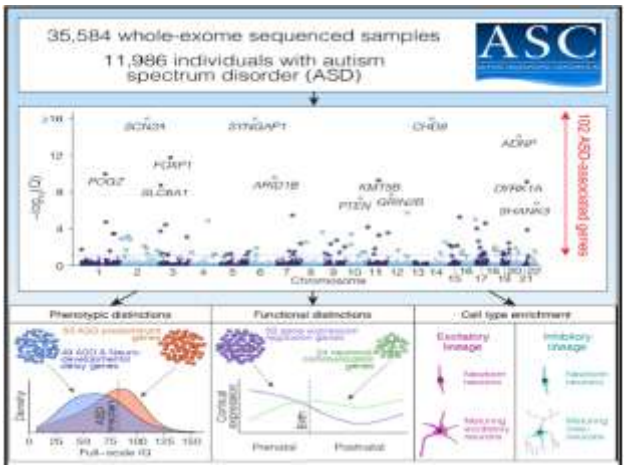
Large-Scale Exome Sequencing Study Implicates Both Developmental and Functional Changes in the Neurobiology of Autism



Highlights

- 102 genes implicated in risk for autism spectrum disorder (ASD genes, FDR ≤ 0.1)
- Most are expressed and enriched early in excitatory and inhibitory neuronal lineages
- Most affect synapses or regulate other genes; how these roles dovetail is unknown
- Some ASD genes alter early development broadly, others appear more specific to ASD

102 geni implicati nel rischio di disturbo dello spettro autistico (geni ASD, FDR ≤ 0,1)

La maggior parte viene espressa e incrementata nelle prime fasi delle linee neuronali (sia eccitatorie, sia inibitorie)

La **maggior parte influenza le sinapsi o regola altri geni**; le interconnessioni non sono ancora chiare

Alcuni alterano ampiamente lo sviluppo iniziale, altri sembrano più specifici dell'ASD

Per la gran parte si tratterebbe di **mutazioni *DE NOVO***

From epigenotype to new genotypes: Relevance of epigenetic mechanisms in the emergence of genomic evolutionary novelty

Carlos Guerrero-Bosagna

Epigenetic changes and the emergence of SNPs and CNVs

Epigenetic changes are known to be influenced by environmental exposures.

Epigenetic changes are reported to influence the emergence of single nucleotide polymorphisms and copy number variations.

This dual ability of epigenetic changes could mean **that germ line epigenetically influenced mutations could have an important role in the emergence of genomic evolutionary novelties**.

I **cambiamenti epigenetici sono noti per essere influenzati dalle esposizioni ambientali**.

È noto che i **cambiamenti epigenetici influenzano l'emergenza di polimorfismi a singolo nucleotide e le variazioni del numero di copie**.

Questa duplice capacità delle alterazioni epigenetiche potrebbe significare **che le mutazioni della linea germinale influenzate epigeneticamente potrebbero avere un ruolo importante nell'emergere di novità genomiche evolutive**.

Le conoscenze emergenti sulla relazione tra cambiamenti epigenetici e mutazioni aiuteranno a comprendere **un ruolo sottovalutato dell'ambiente nella speciazione e nella divergenza genomica: quella dell'influencer dei cambiamenti genomici**

Transposable elements can be seen as a natural genetic engineering system capable of acting not just on one location at a time but **on the genome as a whole** ..This dynamic view of the genome has been illustrated most impressively by *Shapiro* who stated that **the genome is composed of modular units arranged in a "Lego-like" manner that can be altered under circumstances**

Review

A 21st century view of evolution: genome system architecture, repetitive DNA, and natural genetic engineering

James A. Shapiro

Department of Biochemistry and Molecular Biology, University of Chicago, 920 E. 58th Street, Chicago, IL 60637, United States

The last 50 years of molecular genetics have produced an abundance of new discoveries and data that make it useful to revisit some basic concepts and assumptions in our thinking about genomes and evolution. Chief among these observations are the complex modularity of genome organization, the biological ubiquity of mobile and repetitive DNA sequences, and the fundamental importance of DNA rearrangements in the evolution of sequenced genomes. This review will take a broad overview of these developments and suggest some new ways of thinking about genomes as sophisticated informatic storage systems and about evolution as a systems engineering process.

NEURODEVELOPMENT

Somatic mutation in single human neurons tracks developmental and transcriptional history

Michael A. Lodato,[1*] Mollie B. Woodworth,[1*] Semin Lee,[2*] Gilad D. Evrony,[1] Bhaven K. Mehta,[1] Amir Karger,[3] Soohyun Lee,[2] Thomas W. Chittenden,[3,4†] Alissa M. D'Gama,[1] Xuyu Cai,[1‡] Lovelace J. Luquette,[2] Eunjung Lee,[2,5] Peter J. Park,[2,5§] Christopher A. Walsh[1§]

Neurons live for decades in a postmitotic state, their genomes susceptible to DNA damage. Here we survey the landscape of somatic single-nucleotide variants (SNVs) in the human brain. We identified thousands of somatic SNVs by single-cell sequencing of 36 neurons from the cerebral cortex of three normal individuals. Unlike germline and cancer SNVs, which are often caused by errors in DNA replication, neuronal mutations appear to reflect damage during active transcription. Somatic mutations create nested lineage trees, allowing them to be dated relative to developmental landmarks and revealing a polyclonal architecture of the human cerebral cortex. Thus, somatic mutations in the brain represent a durable and ongoing record of neuronal life history, from development through postmitotic function.

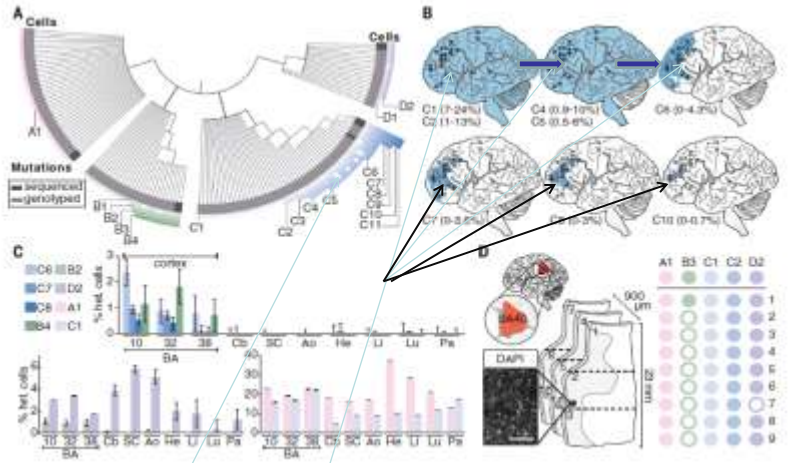

Fig. 3. Somatic mutations are shared between multiple neurons and demonstrate lineage relationships. (**A**) Lineage map of 136 human cortical neurons from brain B derived from 39 clonal somatic mutations, including SNVs, long interspersed nuclear element (LINE) insertions, and a TG dinucleotide expansion. Neurons are placed into four distinct nested clades (pink, green, blue, purple) defined by one or more independent mutations. Cells are ordered within clades according to the presence of multiple somatic mutations. A few cells in each clade fail to manifest individual SNVs shared by other cells of the same clade (indicated by open squares), likely representing incomplete amplification (fig. S2). Dark gray boxes represent cells analyzed by WGS; light gray represents cells analyzed by Sanger-based genotyping. Genomic locations of somatic mutations are given in fig. S3. (**B**) Ultradeep sequencing of mutated loci across the cortex of brain B. Clonal SNVs from a single clade are progressively regionally restricted to frontal cortex and become progressively rarer in bulk tissue, reflecting their later origin during development and neurogenesis. Blue circle, mutation present; empty circle, mutation absent; blue shading, likely spatial distribution of mutation. Percentage range of heterozygous cells is indicated for each SNV. (**C**) Ultradeep sequencing of mutated loci across the brain and body. Some variants are brain-specific (top) and others are shared across germ layers (bottom). Samples sequenced are prefrontal cortex [Brodmann area (BA) 10/BA46], cingulate cortex (BA32/BA8), temporal cortex (BA38), cerebellum (Cb), spinal cord (SC), aorta (Ao), heart (He), liver (Li), lung (Lu), and pancreas (Pa). (**D**) Genotyping shared variants in small sections of human cortex. Left: 4′,6-diamidino-2-phenylindole (DAPI) stain of segment of representative section; scale bar, 200 µm. Center: Three consecutive 300-µm coronal sections from BA46 (red, upper left) were dissected into three axial regions each (1 to 9). Right: Genotyping results for dissected sections. Solid circles denote presence of mutation in indicated sample; open circles, denote absence. Mutations with high allele fractions are present in all or virtually all regions, whereas only the least prevalent somatic variant (present in <0.5% of cells) is present in one region but not most regions.

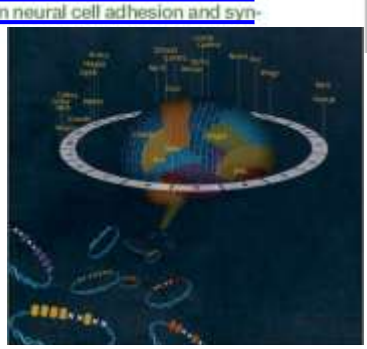
Double-strand break repair is required for neural development, and brain cells contain somatic genomic variations. Now, Wei et al. demonstrate that neural stem and progenitor cells undergo very frequent DNA breaks in a very restricted set of genes involved in neural cell adhesion and synapse function.



Many of the identified genes are **expressed in NSPCs located in the brain regions responsible for higher functions such as short-term learning,** and mutations in these genes in humans are associated with (and maybe predispose to) **psychiatric and neurological disorders manifested in mind functions—autism, manic depressive and depressive disorders, schizophrenia**, and others

In Brief

Neural stem and progenitor cells undergo massive genomic alterations in a very restricted set of genes involved in synapse function and neural cell adhesion, processes that are likely to govern the special behavior of brain cells. Many of these genes have also been implicated in mental disorders.

Highlights

1) **27 Recurrent DSB clusters (RDCs)** are identified **in neural stem/progenitor cells**

2) All RDCs are within genes, most of which are long, transcribed, and late replicating

3) Most RDC genes are **involved in synapse function and/or neural cell adhesion**

4) A nucleotide-resolution view of **replication stress-associated fragile sites** is provided

STRESS PROTEINS AND DNA AS A FRACTAL ANTENNA FOR RFR

DNA acts as a 'fractal antenna' for EMF and RFR.

The coiled-coil structure of DNA in the nucleus makes the molecule react like a fractal antenna to a wide range of frequencies.

The structure makes DNA particularly vulnerable to EMF damage.

The mechanism involves direct interaction of EMF with the DNA molecule (claims that there are no known mechanisms of interaction are patently false)

Many EMF frequencies in the environment can and do cause DNA changes.

The EMF-activated cellular stress response is an effective protective mechanism for cells exposed to a wide range of EMF frequencies.

EMF stimulates stress proteins (indicating an assault on the cell).

EMF efficiently harms cells at a billion times lower levels than conventional heating.

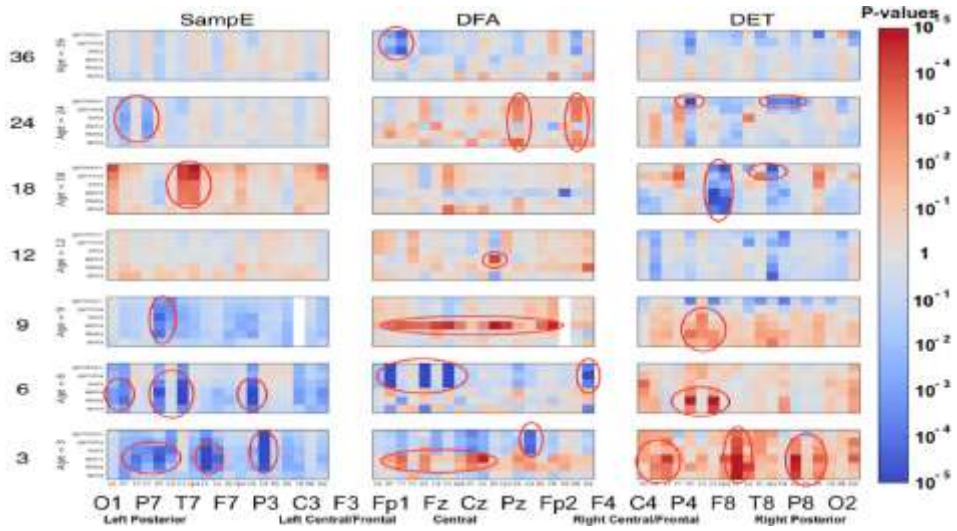
EEG Analytics for Early Detection of Autism Spectrum Disorder: A data-driven approach

Received: 15 August 2017
Accepted: 28 March 2018
Published online: 01 May 2018

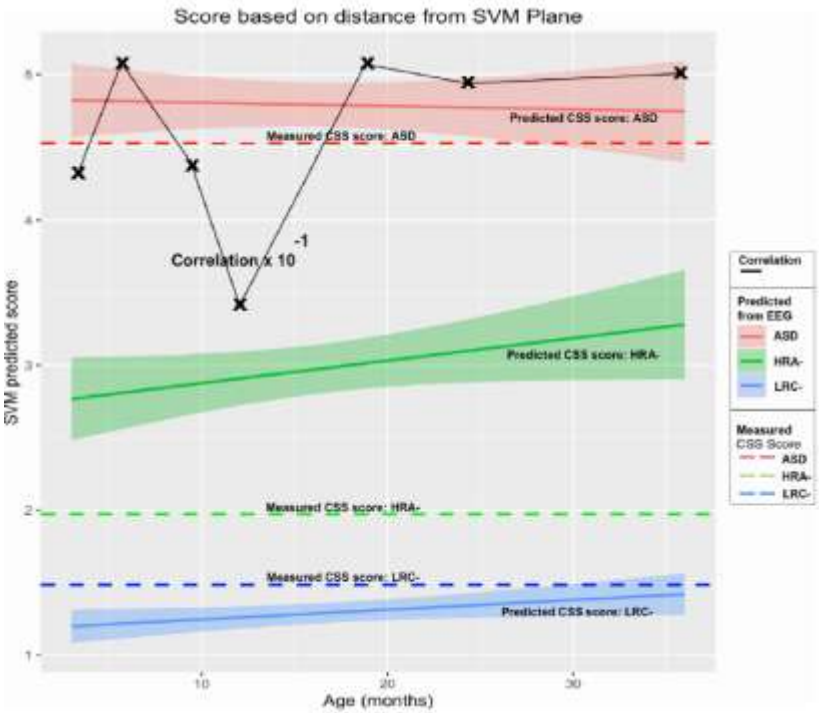
William J. Bosl[1,2,3], Helen Tager-Flusberg[4] & Charles A. Nelson[1,2,5]

Autism spectrum disorder (ASD) is a complex and heterogeneous disorder, diagnosed on the basis of behavioral symptoms during the second year of life or later. Finding scalable biomarkers for early detection is challenging because of the variability in presentation of the disorder and the need for simple measurements that could be implemented routinely during well-baby checkups. EEG is a relatively easy-to-use, low cost brain measurement tool that is being increasingly explored as a potential clinical tool for monitoring atypical brain development. EEG measurements were collected from 99 infants with an older sibling diagnosed with ASD, and 89 low risk controls, beginning at 3 months of age and continuing until 36 months of age. Nonlinear features were computed from EEG signals and used as input to statistical learning methods. Prediction of the clinical diagnostic outcome of ASD or not ASD was highly accurate when using EEG measurements from as early as 3 months of age. Specificity, sensitivity and PPV were high, exceeding 95% at some ages. Prediction of ADOS calibrated severity scores for all infants in the study using only EEG data taken as early as 3 months of age was strongly correlated with the actual measured scores. This suggests that useful digital biomarkers might be extracted from EEG measurements.

L'autismo è difficile da diagnosticare, soprattutto all'inizio della vita. Un nuovo studio su *Scientific Reports* mostra che **EEG** (oltretutto poco costosi) **predicono accuratamente o escludono il disturbo dello spettro autistico (ASD) in neonati di appena 3 mesi**.



Gli **algoritmi computazionali hanno analizzato sei diverse componenti (frequenze) dell'EEG (high gamma, gamma, beta, alpha, theta, delta) usando una varietà di misure di complessità del segnale**.
Queste misure **possono riflettere le differenze nel modo in cui il cervello è cablato e in che modo elabora e integra le informazioni**



I risultati sono stati sorprendenti.. **l'accuratezza predittiva a 9 mesi è stata quasi del 100%,** inoltre si è potuto **prevedere la gravità dell'ASD,** come indicato dal punteggio di gravità calibrato ADOS..

Le **differenze precoci di complessità del segnale**, mostrano **molteplici aspetti dell'attività cerebrale**, e corrispondano all'idea che **l'autismo sia un disturbo che inizia durante lo sviluppo precoce del cervello,** ma può assumere **diverse traiettorie**.

The "MS-ROM/IFAST" Model, a Novel Parallel Nonlinear EEG Analysis Technique, Distinguishes ASD Subjects From Children Affected With Other Neuropsychiatric Disorders With High Degree of Accuracy

Abstract

Background and Objective. In a previous study, we showed a new EEG processing methodology called Multi-Scale Ranked Organizing Map/Implicit Function As Squashing Time (MS-ROM/IFAST) performing an almost perfect distinction between computerized EEG of Italian children with autism spectrum disorder (ASD) and typically developing children. In this study, we assessed this system in distinguishing ASD subjects from children affected with other neuropsychiatric disorders (NPD). *Methods.* At a psychiatric practice in Texas, 20 children diagnosed with ASD and 20 children diagnosed with NPD were entered into the study. Continuous segments of artifact-free EEG data lasting 10 minutes were entered in MS-ROM/IFAST. From the new variables created by MS-ROM/IFAST, only 12 has been selected according to a correlation criterion. The selected features represent the input on which supervised machine learning systems (MLS) acted as blind classifiers. *Results.* The overall predictive capability in distinguishing ASD from other NPD cases ranged from 93% to 97.5%. The results were confirmed in further experiments in which Italian and US data have been combined. In this analysis, the best MLS reached 95.0% global accuracy in 1 out of 3 classes distinction (ASD, NPD, controls). This study demonstrates the value of EEG processing with advanced MLS in the differential diagnosis between ASD and NPD cases. The results were not affected by age, ethnicity and technicalities of EEG acquisition, confirming the existence of a specific EEG signature in ASD cases. To further support these findings, it was decided to test the behavior of already trained neural networks on 10 Italian very young ASD children (25–37 months). In this test, 9 out of 10 cases have been correctly recognized as ASD subjects in the best case. *Conclusions.* These results confirm the possibility of an early automatic autism detection based on standard EEG.

How Music shapes our Brain

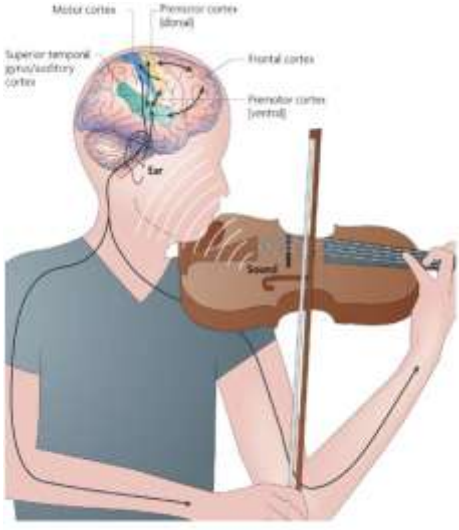
Un caso estremamente interessante è quello del **cervello del musicista** che presenta una **struttura alquanto particolare, almeno nei casi in cui lo studio della musica ha avuto inizio nelle primissime fasi della vita..**

"You are your synapses. They are who you are."
--- Joseph LeDoux, 2002 (in *Synaptic Self*)

Music training can significantly improve our motor and reasoning skills

We generally assume that learning a musical instrument can be beneficial for kids, but it's actually useful in more ways than we might expect.

One study showed that **children who had three years or more musical instrument training performed better than those who didn't learn an instrument in auditory discrimination abilities and fine motor skills**.



08 PLOS ONE ***Practicing a Musical Instrument in Childhood is Associated with Enhanced Verbal Ability and Nonverbal Reasoning***

Some of **the brain areas that have been found to be enlarged in musicians** in morphometric studies based on **structural magnetic resonance imaging**. *Red*, **primary motor cortex**; yellow, **planum temporale**; orange, **anterior part of the corpus callosum**.

Everybody know that **Albert Einstein**, when he was young, **did extremely poor in school…** and that his grade school teachers told his parents to take him out of school because **he was "too stupid to learn"** and it would be a waste of resources for the school to invest time and energy in his education. **The school suggested that his parents get Albert an easy, manual labor job as soon as they could**. His mother did not think that Albert was "stupid". **Instead of following the school's advice, Albert's parents bought him a violin.** Albert became good at the violin. **Music was the key that helped Albert Einstein become one of the smartest men who has ever lived**. Einstein himself says that the reason he was so smart is because he played the violin and **loved the music of both Mozart and Bach** ..

*"I just can't listen to any more **Wagner**, you know...I'm starting to get the urge to conquer **Poland**."*

I'M LOOKING FOR THE ANSWER TO LIFE, SCHROEDER.. WHAT DO YOU THINK IS THE ANSWER?
BEETHOVEN!
BEETHOVEN IS IT, CLEAR AND SIMPLE!! DO YOU UNDERSTAND?
GOOD GRIEF!
